THE Ashton and Green Iron Co., of Bury-street, St. Mary Axe, E.C., have introduced a new stove patented by Mr. E. Wright, which, from our inspection of it, appears to possess many indisputable advantages, amongst them, that it is smokeless, burns coke and anthracite coal, or any rubbish, producing a brilliant fire in five minutes, that it gives out double the heat with less fuel than any other stove, overcomes a sluggish or down draught, prevents draughts from doors and windows, is perfect in combustion, requires no attention, and is quite clean, the fuel being reduced to ashes, &c. These advantages have been confirmed by several gentlemen who have used the stove, including Dr. H. Osborne Grenfell, of Southend. The patent "wywy" stove, illustrated by the section we give, has an independent fresh-air channel, which can be brought direct from the outer air between the joists and turned inwards under the hearth to the underside of the fire-basket, thus supplying all the air to the stove required for combustion, at the same time avoiding all draughts from the room. On the ground floor the channel may be made to end under the first joist next the hearth, the current in this case being supplied through the air bricks, while on any upper floor the duct can be carried between the hearth and ceiling, and be made to extract the vitiated air of the room below, a pipe being taken between two joists to the outer wall. The fresh air is introduced by a grating immediately in front of the ash-pan, and between it and the fire-bars of fire-box as shown. We observe that the fire-basket is shallow, specially shaped, and has a solid front, so that the air is obliged to pass through the bottom of the fuel. The basket, as well as the ash-pan, can be readily taken out for cleaning. Nothing can be simpler than this arrangement. In front of the fire-basket is an ornamental cast front, easily removed. The inlet of channel can be regulated by a ventilator, thus controlling the air supply. On the ground floor a hot-air chamber or oven can be formed below the hearth and stove, thus making a capital cooking oven. The "wywy" can be fitted into a wooden chimney-piece with a loose canopy and a "Teale" shaped solid firebrick back. The stove we saw was fitted with tiles, in the cheeks, had a sloped firebrick back, and nothing can be neater in appearance. The stove can be fitted to the simplest or the most elaborate front, and its artistic treatment is certainly more satisfactory than that of the ordinary stove. We have not the slightest doubt that this new stove will be generally used when it is once known, for its perfect cleanliness, greater heat, and economy. The cost of the stove is within the reach of all.

BRICKS AND JOINTS IN BRICKWORK.

THERE is no constituent part of a building about which so much might be written as of a brick; and what is of greater importance from a practical point of view, there is no part less susceptible to disintegrating atmospheric and other influences, and therefore so durable as a well-burnt brick, an example of which—if we may adduce one so far-fetched—is that of Hillah, a modern settlement on the west bank of the Euphrates, built, as we are informed by a paper on "Recent Assyrian Research," read before the Philosophical Society of Great Britain, of

the excavated bricks and terracottas which have been thrown up in the comparatively recent explorations of the ruins of Babylon, situate on the opposite side of the river. But we are not wanting in examples nearer home—

"Those brickly towers
Where now the studious lawyers have their bowers,
Where whilome wont the Templar Knights to bide,
Till they decayed through pride."

And, later still, the 16th century or Tudor brickwork of Hampton Court Palace, with its well-proportioned niche heads of elliptical plan and semicircular elevation; the Layer Marney Tower and churches of Essex, and the Gray's Inn Hall, Holborn, lately denuded in part of its coat of daub or stucco, revealing the warm deep—and in some portions brindled—colour of 16th-century bricks, most probably produced by the fierce heat of wood-burning, and which are likely to outlast the bricks of more modern manufacture employed in the restoration of the exterior wall facings.

These remarks apply more particularly to the north-west portion of the building on either side of the archway approached from Gray's Inn, not the least pleasing feature of the old facing-bricks of which was their uniformity of size and shape, with a regular thickness of bed and cross joints, for which we look in vain on many of our buildings of more modern erection. The "closures" or quarter-bricks in the heading-course next the window reveals bear evidence, by their regularity of size, of having been cut to a gauge for the purpose of keeping the perpend in the heading courses. This was a sample of the work done when the general contractor or *quondam* builder's clerk did not obtain. The face-joints as originally struck and trowel-cut are unfortunately lost, as they had been hacked to form a key for the stucco coating, now removed, and what remained of the old face-joints was therefore necessarily hacked out, and has been reformed by that *shoddy* process known in the trade as "pointing."

The writer would here appeal to all architects, in the interest of good work and the production of skilled workmanship, to insist on the face brickwork being trowel-struck and cut during the erection of the work, except in winter months, when sharp frosts are likely to occur, when the joints should be raked out at least $\frac{3}{4}$ in. deep, and square with the face, laying bare the edges of the bricks in the full depth of the raking out.

The subjoined are some of the reasons for advocating the striking and cutting of the joints during the erection of the building: Good mortar must be used for laying the face bricks, or a good joint cannot be produced. The face bricks must be wetted before laying them during the dry months, or the moisture will be taken up from the mortar by the dry bricks to such a degree as to make it impossible to properly strike the joint. The face bricks cannot be tampered with by colour or copperas, and are, therefore, likely to be of a better class than for work intended for pointing.

The joints are more durable, as they form one body with the mortar of the wall, instead of a veneering, as in the case of pointing. The joints, if properly trowel-struck and cut, exclude the weather more effectually than if pointed, for the reason that the top and bottom edges in pointing are cut off with a "Frenchman" (*i.e.*, a table-knife filed to a point and turned up at

the end). This tool often cuts into the mortar joint, leaving ragged edges and lodgments for the weather, instead of a full joint, with clean-cut top edge, ironed to a degree of smoothness by contact with the underside of the brick trowel in its passage along the joint in the act of cutting off the top edge. A building in which the joints are struck and cut during erection always attracts a better class of workmen than a building carried up *rough* for pointing, the building thereby benefitting by the employment of additionally skilled workmen.

There is no class of work in the trade upon which the skilled bricklayer prides himself so much as upon the finish of his trowel-struck and cut joint, and though it may seem incredible to the uninitiated, there are numbers of men who have followed for years the calling of the bricklayer who are unable to strike and cut a joint possessed of the distinguishing characteristics of first-class work.

There are some examples of good brickwork in London which might with safety be cited in specifications as the standard and quality of work required. A plan which recommends itself is to build a sample piece of face brickwork in the early stages of the job, as a standard of work below which the contractor shall not go—a practice very largely followed by engineers, and not confined to brickwork only.

Though the practical bricklayer will in nearly every instance declare in favour of the flat struck joint because of the facility it affords him of hiding some of the inherent and acquired defects of the bricks (defects of shape, and of damage by transit), yet there is much to be said in recommendation of the weathered joint now in vogue; and in two pieces of work executed at the same time, all conditions being equal, there is no doubt but that the weathered joint would be found the more durable of the two, on account of its sheltered position with respect to the face of the building. The top edge of the weathered joint should be struck well back—not less than $\frac{1}{4}$ in.—and the bottom ragged edge removed, the joint *slightly* overlapping the top edge of the course below. If the joint is cut *above* the top edge of the course below, the joint is likely to form an arrestment for the weather, and defeat the object of the weathered joint. Where this form of joint is used, it should be borne in mind that a large proportion of our bricks ordinarily used for facings are not only pervious to moisture, but are active inductors of it, by reason of their porous structure and consequent capillary attractiveness. With bricks of this kind the weathered joint is of little or no use, for the rain, though falling free of the mortar joint in its passage down the wall, will be imbibed by the brick courses between joint and joint, until the wall be well charged with moisture. In weathered-struck joint intended to be first-class work, the bricks should be sorted out to a regular thickness by trying each brick to a gauge. The necessity of this arises from the fact that the top edges of the bricks when building are laid or adjusted to the level of the brick-line, drawn from end to end of the wall, and any difference in the thickness of the bricks are, therefore, unavoidably driven into the mortar bed-joint of the course below, and is made very apparent by striking or weathering the upper portion of the joint from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. back from the face of the wall. The flat-struck joint, from its comparatively exposed position, is susceptible to injury, and to apparent obliteration by sooty deposits in our large manufacturing towns, losing the interest and units of measurement, which the joints, more than anything else, impart to a piece of work; while the weathered joints, with their play of light and shade, always remain distinctive features, or indices of construction.

(To be continued.)

RAPID BUILDING IN CHICAGO.

THE British Consul at Chicago in his latest report gives an example of the extraordinary rapidity with which lofty buildings are erected there. The Ashland block, a construction of steel, stone, and terracotta at the corner of Randolph and Clark streets, close to the city hall, 17 stories in height, was built on an area of 140ft. by 180ft. in midwinter, and work was continued, day and night, by relays of men, strong arc electric lights being used by night; artificial heat was furnished by 100 salamander

stores to enable the builders and masons to work at that season of the year, and protection from cold winds was given by several hundred yards of thick canvas. The skeleton of steel for each floor was first erected, each column, girder, and rafter being lifted and placed in position by steam power; these were riveted with red-hot rivets, and as the stories rose they were filled in with square blocks of terracotta and brick. On December 6 last year six floors were completed, and the steel skeleton for the next six stories was for the most part placed. On December 19 ten floors were completed, and the steel shell for three more stories was mostly in position. Thus the entire construction of four floors of a building 140ft. by 80ft., divided into numerous rooms, was solidly built in 12 days, or one floor in three-and-a-quarter days. About 60 iron and steel workers, 100 brick masons, and 35 terracotta setters were continually at work. The enormous quantity of iron and steel used in this new mode of construction, which was only first tried six years ago, has created quite a new industry, and the *employés* have already their organisation under the term of architectural iron workers. Steel has now almost entirely taken the place of iron, of which the first few of these tall buildings were constructed. The foundations are tiers of steel rails, embedded in concrete, the beams stretching 10ft. or 12ft. under the street. This plan was found necessary on account of the nature of the soil, so as to bear the great imposed weight. These beams are made at the Illinois steel works, or come from Pennsylvania. This new method of building is said to be lighter and stronger than the old system, and to be absolutely fireproof. The greatest variation in the plumb-line from base to top of these tall buildings has been found not to exceed half an inch.

CHIPS.

Lord Balfour of Burleigh, convener of Clackmannan County Council, opened a new iron bridge spanning the Devon at Westhough, on the Alva estate, on Saturday. The bridge is on the lattice girder principle, partly malleable iron and partly steel, the abutments being of stone built on concrete. It has been constructed to bear a weight of 12 tons. The estimated cost is about £1,300. Mr. Lake, county road surveyor, prepared the designs.

On Wednesday week Mr. Arnold Taylor, an Inspector of the Local Government Board, held an inquiry at Ramsgate into an application by the town council to borrow £19,168 for public improvements. The most important item was £13,500 for the purchase and laying out of the Ellington estate as a public park and recreation ground—a proposition which has met with the unanimous approval of the ratepayers.

Premises in Corn-street, Bristol, are being reconstructed for the use of the Wilts and Dorset Banking Company. Mr. Sillery, of Craven-street, Strand, W.C., is the architect, and Mr. E. T. Hatherley, Stokes Croft, Bristol, the contractor.

The East Ham local board have accepted a tender of £2,975 from Mr. Jackson, of Plaistow, for the construction of a northern main sewer for the Manor Park district.

The Llandudno commissioners have decided to call in an expert engineer to advise upon a scheme of sewerage for the district prepared by their surveyor, Mr. E. P. Stephenson, and provisionally adopted by the board.

Mr. F. H. Tulloch, A.M.I.C.E., and Inspector of the Local Government Board, held an inquiry at Beckenham on the 23rd ult., as to the proposal of the local board to borrow £4,637 to execute certain public and private street improvements, and to contribute £100 towards the purchase of the manorial rights in West Wickham Common, with the view of preserving it as a public open space. It was stated that towards the purchase price, £2,000, £1,000 had been privately subscribed, and £500 had been contributed by the Corporation of London, who proposed to come down and hold a formal opening. The inspector said he would report in favour of the proposed contribution.

At Great Carlton, the east window has been filled with stained glass representing the risen Saviour at the open tomb, a memorial of the late Canon Petyman, for 41 years rector of the parish. The artists were Messrs. Powell, of Whitefriars.

A meeting of creditors has been held in the case of Edward Morgan How, builder, of Barry Docks, late of Cardiff, whose statement of affairs shows gross liabilities of £2,520, of which £1,203 is expected to rank, while the assets are expected to produce £50. The debtor has been adjudicated a bankrupt.

Building Intelligence.

A MUNICIPAL LODGING-HOUSE IN DRURY-LANE.—A correspondent of the *Daily News* describes in detail the model lodging-house now in course of erection for the London County Council in Parker-street, Drury-lane. It is being built from designs by Messrs. Gibson and Russell, of Little Queen-street, whose designs were selected in competition. The buildings were estimated to cost £12,000, but this amount has been somewhat exceeded by modifications effected in the plans. The contractors for the building are Messrs. Holloway Brothers, of Battersea, and the clerk of the works is Mr. R. H. Kelland. The lodging house will consist of three blocks connected in the front and at the back, but separated in the middle by two courtyards, and accommodation is provided for 324 lodgers. On the ground floor will be a kitchen 63ft. by 32ft., and 13ft. 6in. in height, dining-room and day room, a work-room lavatory, and laundry accommodation. On the three upper floors are dormitories divided into cubicles, separated by corrugated steel partitions, and warmed by hot-water pipes. The corridors are laid with granolithic paving, and the large rooms on the ground floor with wood blocks.

GLASGOW.—The extensive additions which are being made to the General Post-office, George-square, Glasgow, at a cost of £30,000 will be completed in the course of eighteen months. The post-office was only built in 1879, but is now being enlarged for the second time, and will be doubled in size by an addition at the rear. The present building is not in any way interfered with, except in so far as is necessary to connect it with the new structure in the rear. Having its front elevation towards Ingram-street, it has not been necessary to adhere to the original style of architecture in the new building. The architect, Mr. W. W. Robertson, of Her Majesty's Board of Works, has therefore adopted a Renaissance style. Of the extensions, the main feature is the provision of three large rooms, each 128ft. by 80ft. in the clear, occupying the whole of one of the floors. On the ground floor there will be a new sorting room, and on the first floor is a new letter-carriers' room, and over it again is the telegraph room, with large roof-lights in addition to the windows. The sorting and letter-carriers' rooms are 21ft. in height, the telegraph room has a height of 25ft. In each, too, save by half a dozen supporting columns, the floor space is uninterrupted. The basement is taken up with the engine-room and the boiler-house required for the working of the pneumatic tubes, and the supply of the electric-light. In the basement also accommodation is found for the telegraph delivery room and the telegraph messengers' kitchen. The contractors are Messrs. M'Kessock and Son, Glasgow, and Messrs. Morrison and Mason, Glasgow.

NEWPORT, MON.—Banking premises have just been erected at the lower end of High-street for the National Provincial Bank of England. The façades are of Box and Monk's Park Bath stone above a plinth of Devon granite. The bank building shows five bays in High-street, and a corresponding number in Tredegar-place. The principal enrichment to the exterior is the sculptured floral frieze above the second story window, which runs along the greater portion of both fronts of the building. The floors are fireproof, the joists consisting of iron, filled with Portland cement and concrete, and the flooring is of oak-block and mosaic. The bank-room is 42ft. square, and is surrounded with pilasters of Devonshire marble, with bases of faience work, and Caen stone capitals of the Ionic order. The dado is also of faience work. The panelled ceiling is of adamant plaster. The strong rooms, three in number, are lined throughout with white glazed bricks. The whole of the work has been carried out by Mr. John Linton, builder, of Newport, working from plans prepared by Mr. C. R. Gribble, architect to the banking company. Mr. Thomas Colley, of Clapham, is the sculptor.

TEMPLE-STREET, E.C.—The Law and City Courts Committee of the Corporation of London, to whom it was referred to give directions for the preparation of plans for the erection of Ward's City of London School for Girls, have presented a report to the Common Council on the subject. The site chosen for the proposed school buildings is situated on the east side of the street between

Temple-street and the Victoria Embankment roadway, and is adjacent to the Guildhall School of Music. The City Surveyor, Mr. Andrew Murray, laid before the committee drawings, showing plans and sections for the proposed school, and also six alternative elevations, together with estimates of the cost of the building and fittings. The plans provided for the accommodation of upwards of 400 pupils, and the committee recommended that the plans and sections, together with the elevation in the Gothic style, be approved by the Court of Common Council, and that they be authorised to give directions for the erection of the school in accordance therewith, at the cost estimated by the City Surveyor—viz., £15,400, and an additional sum of about £2,000 for fittings.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The forty-ninth congress of this association, held at Cardiff last week, was brought to a close on Saturday. On Thursday morning the members visited Caerleon. Mr. Loftus Brock conducted the party to the Roman amphitheatre and the camp, making various comparisons with the Roman stations at Caer Went, Caerleon, and Cardiff, and the museum of Roman and Celtic objects found at Caerleon was visited. Another section of the society assembled at Cardiff Castle, where they were met by Mr. E. W. M. Corbett, who conducted them through the castle, and pointed out the Roman remains in the grounds, the foundations of the house of Black Friars, of which little beyond the ground plan of the walls remains, and Herbert House, built on the ruins of White Friars. A few of the members made their way to the Cardiff Museum to see the antiquities found at Penarth, Barry, Llantwit Major, and other places. In the afternoon the party visited the church of St. Fagans. On the lawn of the castle close by is placed a large leaden cistern measuring 20ft. in circumference and 3ft. 8in. high. This is said to be one of the finest specimens of ornamental lead casting extant; it bears the date 1620, and was found in an inclosure not far distant. The party then proceeded to Talygarn, at the invitation of Mr. G. T. Clark, where a large collection of armour and weapons was shown. The evening meeting was abandoned on account of the late return of the party.—On Friday the members were conveyed in brakes to see the Cromlechs of Dyffryn and St. Nicholas, near Cardiff, which were described by Mr. Franklin G. Evans. Thence the party went to Llancarvon Church. At the church at Llantwit Major, with its inscribed crosses, the guide was Mr. Nicholl, F.S.A. The party then visited Fommon Castle, the seat of Mr. O. H. Jones, who gave an account of the building.

A new Free Presbyterian church was opened at Cowdenbeath by the Rev Dr. Stalker, Glasgow. The church has sitting accommodation for 600 worshippers, and has, with a hall adjoining, been erected at a cost of £2,000.

A marble bust of Dr. Alexander Bain, presented by subscribers in recognition of his services in connection with the establishment of the Public Library in Aberdeen, was unveiled on Friday in the reference room of the library. The bust is the work of Mr. H. Bain Smith, of London.

At the new Springburn Public Park, situated at Balgray Hill, Glasgow, on Friday, Mr. James Reid, of Hyde Park Locomotive Works, formally presented a bandstand to the Springburn district of the city. The stand is an octagonal one of iron with Corinthian pillars, and is adorned with shields bearing the city arms, and the park in which it is placed is 56½ acres in extent and cost the corporation about £21,000. It is intended to fringe the outskirts of the park with a single terrace of dwelling-houses.

The members of the Hampshire Field Club spent an interesting day in the Isle of Wight on Wednesday week. Newport was the rendezvous, where, at eleven o'clock, a party of sixty, including contingents from Southampton, Romsey, Winchester, and Portsmouth, as well as the Isle of Wight, gathered, and proceeded in brakes to Gatoombe. Here the parish church was described by the Rector, and afterwards three manor-houses were seen—that at Sheat, containing a Jacobean oak-panelled room; that at Billington, where the oak staircase was of the Queen Anne period; and that at Kingston, another Jacobean building. Kingston, Shorwell, and Carisbrooke churches completed a full and interesting programme.

Engineering Notes.

BARNTON, NEAR EDINBURGH.—The works on this branch line of the Caledonian Railway system, which is intended to open up Barnton estate for feuing, continue to make good progress. The total length of the line is about 2½ miles, and this has all been roughly formed. In all about 93,000 cubic yards of cutting have been executed, or about 75 per cent. of the whole. There are to be two passenger stations on the line—at Bartongate and Cramond Brig.

BURGHHEAD AND HOPEMAN RAILWAY.—The Highland Railway Company have nearly completed the extension of their Burghhead branch to the quarries of Cummingstown and the harbour of Hopeman. The new line, which is two miles and one-third in length, for the greater part of the distance from Burghhead to Hopeman skirts the seashore, and passes through Greenbrae Quarries, supplying a fine yellow stone much used for building purposes in the north. At the west end of the quarries Cummingstown Station will be erected. The line then runs on to the harbour at Hopeman. At Burghhead a new passenger station is also being erected at the south end of the town, and the present station will be devoted to goods traffic.

THE METROPOLITAN EXTENSION TO AYLESBURY.—The extension of the Metropolitan Railway Company's system from Chalfont to Aylesbury was opened yesterday (Thursday) morning for traffic. This extension, which was sanctioned by Parliament in 1881, commences by a junction with the line recently opened to Chesham, about midway between Chalfont-road Station and Amersham. From this junction the railway proceeds to Amersham, where the first station on the new extension is placed. From thence the line passes through Piper's Wood, Lott's Wood, Little Missenden, to Great Missenden, where the second station on this extension is erected a little to the north of Abbey Park. Running thence in a slightly north-easterly direction to Wendover, where the third station is placed, the line proceeds to the fourth station on this new railway, at Stoke Mandeville. From thence the railway passes in a direct line to Aylesbury, where a temporary station has been erected pending the construction of a permanent joint station. The whole of the skylights over platforms, goods stations, &c., on the line have been glazed on W. E. Rendle and Co.'s patent system. Although this line has been constructed at the cost of the Metropolitan Railway Company, and completes the whole of the northern extensions of that company at present authorised by Parliament, the railway is practically part of the still greater scheme by which the Manchester, Sheffield, and Lincolnshire Railway will be brought into London, and the Bill for which only awaits third reading in the House of Lords and the Royal Assent to be passed as an Act.

CHIPS.

The new hospital, Dunedin, New Zealand, is being warmed and ventilated by means of Shorland's patent double-fronted Manchester stoves with descending smoke-flues. The same being supplied by Mr. E. H. Shorland, of Manchester.

Stained glass has just been inserted into one of the windows in the nave of Idle Church, in memory of the late Mr. Benjamin Thornton and his wife, by their daughter, Mrs. Fletcher, of Idle. The work is from the studio of Messrs. Powell Brothers, of Leeds.

A church to seat 450 is being built at Castlebay, Island of Barra, by the Home Mission of the Church of Scotland, for the accommodation of the parishioners and fishermen coming to the island for the fishing season. The church is built of the local gneiss, with dressings of Portland cement concrete, in Lancet Gothic, with open-timbered roof, from designs by Messrs. Hardy and Wight, architects, Edinburgh, to cost about £1,100.

A new fire-station, erected at a cost of £14,000, was opened at Leicester on Tuesday.

The congress of master builders, held at Kiel, was forcibly dissolved by the police authorities on Tuesday as a precaution against the spread of the cholera.

The governors of University College, Dundee, have decided to enlarge the building erected ten years ago by the addition of an eastern wing containing classrooms, and the improvement of the front elevation of the existing buildings. The estimated outlay is £5,000.

TO CORRESPONDENTS.

(We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.)

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of THE BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASMORE EDWARDS.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL., XLI., XLVI., XLIX., L., LI., LIII., LIV., LVIII., LIX., LX., LXI. and LXII. may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—F. R. Bros.—J. R. Co.—B. and M. T. Co.—Surveyor.—Thos. Jacques.—Benj. D. (Lincoln).

Intercommunication.

QUESTIONS.

[10397].—**National Gallery.**—How is permission gained to photograph pictures in the National Gallery? I see reproductions offered for sale by different reproductive processes. Is permission to do this obtainable?—N.

[10398].—**Hoisting Drum.**—Some time ago, when in London, I saw from a distance a large wood drum turned by two men. This was used for raising barrows containing bricks, one barrow descending empty as the loaded barrow ascended. Would some of my fellow-readers who have adopted this arrangement kindly, through this paper, give me sketch, dimensions, and all particulars of drum and frame?—A. B.

[10399].—**Brickworks.**—Will a square chimney stack 90ft. high, 7ft. by 7ft. inside at base (divided by a 9in. fire-brick partition 14ft. high), and diminishing to 4ft. by 4ft. at top, produce a sufficient draught to work the flues (1ft. 3in. wide by 9in.) under the drying sheds (having a superficial area of 11,300ft.), the longest of which being 222ft., and the shortest 147ft. before entering the stack? Also would there be any doubt as to the successful working of another set of flues (2ft. 3in. wide by 1ft. 4in. high) immediately below, and connected with the upper ones, thus making the flues nearly twice the length? The works are not yet erected, so that advice would be appreciated; also as to the best size stack in each case, &c.—W. T. E.

[10340].—**Sewage.**—Will some fellow-reader kindly inform me the name of the best book or books treating of sewage from the time it leaves the house; also the best book on water and hydraulic apparatus, with the prices of each, and oblige—SANITAS.

[10341].—**Books.**—I would be glad to know of some really first class books on Renaissance detail, with some idea of price.—ARCHITECT.

REPLIES.

[10396].—**The Chester Rows.**—Hemingway, in his valued "Hist. of Chester," published 1831, says: "To trace the origin and cause of these Rows with any degree of certainty is no easy task, concerning which a variety of conjectures have been formed. Some have attributed their origin to the period when Chester was liable to frequent attacks from the Welsh, which induced the inhabitants to build their houses in this form, so that they might avoid the danger of the horsemen, and annoy their assailants as they passed through the streets. I am

aware that this has long been, and still is, the popular sentiment; but I think there is irrefragable evidence that the form of our city is Roman, and that the walls were the work of that people." Pennant appears to have been governed by this view. He says: "These Rows appear to me to have been the same with the ancient vestibules, and to have been a form of building preserved from the time the city was possessed by the Romans, and were the places where dependants waited for the coming out of their patrons."—A. L., Chester.

Legal.

LIABILITIES OF LOCAL BOARDS.

IT has once more been decided by the House of Lords, in a recent case affecting the New-market Local Board (*Times*, August 10), that a local board cannot be made liable in an action for damages for personal injuries sustained through non-repair of the highway. The facts of the case were simple enough, and such as may at any time be repeated. The plaintiff, going along a footpath, part of the highway, on a dark and rainy night, fell by reason of a slope which had been cut as an entrance to a stable yard. The ground of complaint against the local board was that they had passed the work, including this slope, as satisfactory, and had not taken care to have it protected by a dwarf wall, or to have the place properly lighted by putting a street lamp near to the spot. The jury had found that the footpath was not sufficiently lighted, and gave a verdict for the plaintiff with damages. But the Judge who heard the case set aside their verdict on the ground that the local board had not neglected any duty imposed upon them, nor done any affirmative act for which they were responsible, and the Court of Appeal confirmed this ruling.

The House of Lords now took the same view; but they based their decision upon broader grounds. They decided that where a roadway ought to be repaired by the public through the surveyor of the local authority, no action for damages for injury can be maintained against that authority for an accident arising from their neglect. In this case the ground of action was really the defective construction of the entrance to the stable forming a portion of the public footpath. The plaintiff, therefore, failed entirely in his action, as he could not show that the local board had failed in any particular duty, or were in any way bound to place a lamp-post to light that special spot. Possibly there would have been some ground for proceeding against the local board, or its highway surveyor, by indictment for a nuisance; but at all events, there was no ground of action for damages to a private individual in such a case.

FRED WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

A. G. F.—**DRAINS—EASEMENT.**—It would seem that B' has acquired a right of way over A's land for his drain, both by long user and by A's own acquiescence. The best way out of the dilemma would be to call in the sanitary authorities, who would probably require that B. should construct a separate drain to the common sewer on his own ground, and not under A's house, if that is possible.

C. O. S. and S.—**BUILDING CONTRACT—SCHEDULE OF PRICES.**—This schedule of prices is referred to in, and so is made a part of, the contract; and each party thereto should properly have had a copy of that schedule. It appears to have been the intention of the parties that this schedule itself should be left in the custody of the architects engaged, and I do not consider that they can be bound to part with the original. But they might let the employers have inspection, or, even, a copy at their own expense.

Z. O. M.—**DRAINAGE—RIGHT OF WAY.**—The question whether your neighbour B. has any right of way over your land for his drainage must depend on the respective deeds under which you both hold the property. But he certainly cannot compel you to find larger pipes for his convenience. The shortest and simplest way out of the difficulty would be to get the sanitary inspector to condemn the old system of a connected drainage, and insist on separate pipes.

A Local Government Board inquiry has been held at Marehay, near Belper, before Mr. F. H. Tulloch, A.M.Inst.C.E., with reference to an application made by the Belper Rural sanitary authority for permission to borrow £3,700 for the purchase of land for sewage disposal. Mr. Robert Argyle, C.E., of Ripley, Derbyshire, is the engineer of the scheme adopted.

LEGAL INTELLIGENCE.

IS A TIMBER STAGE A "BUILDING"?—James Smith, builder, of Romford-road, Manor Park, was summoned to the North London police-court on Friday by Mr. Legg, district surveyor of Hackney, for erecting a building at No. 33, High-street, Kingsland, with walls constructed of brick or stone, and covering the roof with slates or tiles and providing proper foundations, as required by the Building Act of 1855. The building in question was a large erection, part shop, part timber stage, near Dalston Junction, and when the district surveyor called the defendant's attention to the fact that he had not given the required notices the reply was that it was not a building—it was merely a timber stage. The owner of the structure (Mr. Tappin) was first summoned; but on the present defendant admitting himself to be the builder, the original summons was dismissed, and the present one taken out. The structure is 17ft. wide, 42ft. long, and 32ft. high; it stands upon timbers for a foundation, and has revolving shutters at the lower portion, and in this are retained, besides lengths of timber, various wooden manufactured goods, such as meat safes, cornice poles, step ladders, &c. Mr. Corser, in giving his decision, said this was clearly a contravention of the Building Act. He was not going to say all timber stages are buildings; but, from what he had heard and seen of the structure in question, he came to the conclusion that it was a building within the meaning of the Act, and that the requirements of the district surveyor must be complied with. Mr. Justice Byles, in an elaborate decision on the oft-debated question as to what is a building, said each case must be taken on its merits. This structure was permanently used as a shop, and was abutted on by houses and shops wherein people resided. It had been pleaded that the sides of the structure were not inclosed; but this suited the particular trade, and could not be an argument against the assertion that the place was a shop. The order would be to comply with the district surveyor's requirements.

CLERKS OF WORKS' OFFICES AND THE BUILDING ACT.—At Lambeth Police-court on Tuesday, Mr. John Fyfe, of the Estate Office, Electric-avenue, Brixton, appeared in answer to an adjourned summons for having set up a certain structure of a movable or temporary character without the license of the London County Council. Mr. T. Chilvers stated that defendant had already been fined for the structure in question. The defendant afterwards applied to the Council for a license, but they refused to grant it. The defendant had not removed the structure, and up to the date of the summons he had incurred penalties amounting to £46. Mr. Kingsbury, for the defence, said the defendant was under a misapprehension. The structure was an office put up for the use of the clerk of works, but the defendant was ready to undertake to pull it down immediately. Mr. Biron said he would reduce the pounds to shillings on the understanding that the structure was pulled down in a week. He fined the defendant 46s. and 42s. costs.

Mr. Till, the city surveyor of Birmingham, is trying experiments with a new sewer ventilating apparatus which he has had erected at the junction of Hayley and Clarendon-roads in that city. It is one of the many forms of combined street lamp and sewer ventilator, and has an attenuated conical iron cap rising above the pipe.

At the London Consistory Court, on Monday, Dr. Tristram was asked to grant an application for a faculty for rebuilding the Church of St. Peter, Regent-square, and providing schools, mission buildings, and vicarage house upon the site; or, in the event of this not being adopted, for the faculty to underpin and repair the existing church, taking down galleries, and to separate a portion of it for parochial purposes. It was stated that the church has fallen into a condition of great decay, and that reconstruction or extensive repair is absolutely necessary. The Chancellor reserved judgment.

An inquest was held at Woolwich, on Tuesday, into the death of William M. Forbes, 45, a bricklayer and retired sergeant of the Royal Engineers. A foreman and three bricklayers were at work in the Royal Arsenal gas factory erecting the archway of a new retort, when, on striking the centre of an arch which had just been built, the structure fell, and deceased was buried under 40 tons of debris. Two other men were injured, one of whom, Henry Flowers, appeared on crutches to give his evidence, the third man, William Hunt, being unable to leave the infirmary. The accident was attributed to the work being green, and to the arch being struck before some iron stanchions had been affixed to it. It was stated that the foreman was competent for the work, though there had been an error of judgment committed by the arch being struck too soon, and before the supports had been put up. The jury were of opinion that Forbes came by his death through an error of judgment on the part of the foreman, Daniel Tytheridge; but that there had been no criminal negligence.

WATER SUPPLY AND SANITARY MATTERS.

ANNAN, N.B.—A meeting of the Annan district committee of the Dumfriesshire county council was held on Friday in the town hall. An extensive scheme for the supply of water to the numerous villages and farms in the district was considered. The proposal was to construct a reservoir on the Mein at Torbeckhill, 526ft. above sea level, with a storage capacity of 30,000,000 gallons, and to distribute the water by main pipes laid along the public roads over a radius extending from Springfield on the east to Locharwoods and Dalton on the west. The district was surveyed by Mr. James Wilson, C.E., Greenock, who estimated the cost of the scheme at £38,000. The sub-committee who recommended the scheme calculated that the annual burden would be £2,400. After discussion, further consideration of the scheme was adjourned until a plebiscite has been taken.

CHIPS.

Two new halls at Folkestone, for the Church Congress in October, are being actively pushed forward in the Exhibition Palace grounds, the larger of which will seat 3,000 members. The Ecclesiastical Art Exhibition will occupy part of the palace.

The trustees of Finsbury Chapel, near Broad-street Station, having surrendered their lease to the Corporation, the site is now in the market on a building lease.

A fire broke out on Saturday under the stage of the Metropolitan Opera House, New York. The firemen were able to save the façade of the building with its business premises; all the rest was destroyed, and the damage is estimated at between one and two hundred thousand dollars.

At the half-yearly meeting of the shareholders in the Manchester Ship Canal, held on Tuesday, the directors' report, which admitted that the new estimate shows the necessity of taking steps at once to obtain further Parliamentary powers to raise at least £1,500,000, in addition to the capital already authorised, was confirmed. Lord Egerton of Tatton, the chairman of the company, urged that by reason of unforeseen contingencies the estimates had necessarily been increased from time to time; but he confidently hoped for the completion of the waterway by the end of 1893. He had never less despaired of the future of the canal than at the present time.

A church, to be dedicated to St. John, is about to be built at Ripley, Derbyshire, from plans by Messrs. Naylor and Sale, of Derby and Lincoln. The estimated cost is £2,700, of which more than two-thirds has been raised.

The water-colour painter, Rudolph Alt, who is widely known by his architectural pictures, mostly of Vienna and Venice, entered his eightieth year on Sunday. The event was celebrated by a banquet given by the Vienna artists, and by the opening of a special loan exhibition of Alt's water-colours. Although not complete, it already numbers 528 works, from the first, painted in 1829, to the last, only just finished, representing the Radetzky monument and its surroundings.

Foundation stones of a Conservative clubhouse were laid at Clayton, near Halifax, on Saturday. Mr. S. Spencer, of Great Horton, Bradford, is the architect, and the cost will be £1,700.

The first mayor of the newly-created borough of Thornaby-on-Tees (late South Stockton) will be Mr. William Anderson Magin, of the firm of Head, Wroughton, and Co., bridge builders, who is also appointed under the charter provisional mayor to carry out the preliminary proceedings, and conduct the first meeting. Mr. Magin is the present chairman of the local board.

Two stained-glass windows have just been unveiled in St. Stephen's Church, Bowling, Bradford. "Our Lord's Sermon on the Mount" and "Disputing with the Doctors" are the subjects illustrated. They are from the studio of Messrs. Powell Brothers, of Park-square, Leeds.

New swimming-baths at Wellingborough were formally opened last week. Messrs. Duley and Sons were the contractors.

The last of the season's excursions of the Archaeological section of the Birmingham and Midland Institute took place on Saturday, when a visit was paid to Nottingham Castle and Wollaton Hall. Mr. A. Marshall, architect, of Nottingham, met the party and acted as guide.

The Trafalgar-square Theatre, St. Martin's-lane, erected from the designs of Mr. Walter Emden, will be opened on Monday week, the 10th inst. It is isolated on three sides, is Italian in style, and has a chief frontage of brick and stone. Internally the house consists of four tiers, and seats 1,250 persons. The theatre was illustrated in our issues of Nov. 27, 1891, and March 25, 1892.

Our Office Table.

THE autumn exhibition of the Royal Birmingham Society of Artists has just been opened, and is of more than average interest. Among the most noteworthy pictures are the "Sic Transit," by G. F. Watts; "The Kiss," "Phidias and the Elgin Marbles," and "A Roman Amateur," all by Alma Tadema; some Italian subjects by W. Aumonier, Adrian Stokes, and Henry Wood; W. Logsdail's realistic "Ninth of November." Among the portraits may be singled out those of J. R. Pettie, R.A., by A. S. Cope; Val Prinsep's "Black Pearl," and Herkomer's powerful "Board of Directors," which attracted so much attention at Burlington House this spring. The best landscapes are contributed by H. W. B. Davis, David Murray, Alfred East, F. G. Cotman, Ernest Parton, and C. E. Johnson. Of the humorous subjects "Between Two Fires," by F. D. Millet, lent by the Chantrey trustees, and "The Skipper Prescribes," by Albert Sterling, are the best.

The autumn exhibition in the City Art Gallery at Manchester will be opened on Tuesday next, the 6th inst. Among the portraits that of Mr. Alfred Waterhouse, R.A., by Alma Tadema, hung at the recent Academy, will be of the greatest interest in the city which counts as its chief architectural adornment the Town-hall reared from Mr. Waterhouse's designs. Other works from the late Academy show are Stanhope Forbes' "Forging the Anchor," Val Prinsep's too-theatrical "Broken Idol," and "The Annunciation," by Arthur Hacker, deservedly purchased by the Chantrey Fund.

An exhibition of laundry and other appliances at the Central Hall, Holborn, closes tomorrow. There is not much there worth attention. The visitor will not fail to notice in the centre of hall Messrs. Doulton's stand, where may be seen in operation an apparatus for softening water, specially adapted for laundry purposes. The Blackman Ventilating Co. (Limited), Fore-street, London, &c., show several fans and a tubular air-warmer. The Blackman system of rapid drying for laundries, &c., is an important exhibit. A dry wind produced by a fan is used, and the apparatus we saw is placed on brickwork, and is capable of sending out a dry wind of 140° or more. The time of drying a blanket from the hydro is from 30 to 40 minutes, and for cotton goods from 15 to 5 minutes, according to substance. By this very economical system and apparatus, which can be applied to any room, a constant supply of dry air is obtained, and the drying is effected at a very considerable reduction of cost.

The official list of the successful candidates at this year's "examination" in connection with the Westminster School of Art at the Royal Architectural Museum, has just been published, showing a record which will compare with any other similar school in the country. Eleven obtain "first-class excellent" for drawing from the life; twelve "first class," and forty-three "second class." Three obtain "first-class excellent" for drawing from the antique, twelve "first class," and twenty-eight "second class." In the memory drawing from the antique, composition from a given figure subject, plant drawing, still life and anatomy, good results are also shown. In the second-grade examinations the pupils are not so numerous. A silver medal in the National competition is obtained for a modelled design for wall decoration by Fredk. J. Langer. Queen's prizes are taken by five students, and three others for fine modellings from the panel or cast obtain national book prizes.

THE Bristol City Council have just received a report from their finance committee as to the accommodation required for municipal offices. Two years ago the council purchased the property at the corner of Corn-street and Broad-street, adjoining their present Council-house, as a site for extended offices; but although a committee then recommended that competitive designs for the proposed new buildings be invited, the cost to be restricted to £80,000, no further steps have been taken. They now report that the accommodation required would include a council chamber, 50ft. by 32ft.; a committee-room, 28ft. by 16ft., and two smaller rooms; and five rooms for the chief officials, each 22ft. by 16ft., with smaller rooms attached *en suite*, while desirable additions would

be a public hall and a gallery for the exhibition of pictures, all of which accommodation could be provided on the property now in the possession of the council. Consideration of the report has been adjourned.

The annual meeting of the Royal Victorian Institute of Architects was held on July 19 last, Mr. G. C. Inskip, F.R.I.B.A., President, occupying the chair. The annual report and balance-sheet were read and adopted, and the president read a valedictory address, in the course of which he advocated the federation of all the Australasian societies representing architects, and congratulated the members on the fact that the Registration of Architects Bill, unanimously adopted by a joint committee of the Institute and outsiders, was now before the Victorian Parliament as a Government measure. The election of office-bearers for the ensuing year resulted in Messrs. A. E. Johnson and P. Oakden being elected as vice-presidents, Mr. W. Lucas as hon. treasurer, Mr. W. U. Billing as hon. secretary, and Messrs. F. Purbrick, W. B. Tappin, and R. G. Hyndman as the council.

At the last meeting of the French Académie des Inscriptions, M. Toutain gave details as to the Roman Theatre of Simithu, at Chemtou, Tunis, which he has recently been excavating. This theatre has several peculiarities of construction. The lower part of the semicircle of seats, which was completely covered up when M. Toutain commenced his excavations, is very well preserved, and the place occupied by the orchestra has a mosaic pavement representing all the varied colours of Numidian marble. The stage has not yet been excavated, but in the course of the researches already made several coins of the reign of the Emperor Philip have been discovered, as well as fragments, showing that the theatre was transformed into dwelling-houses before it was left to go to ruin.

The Architectural Association.—September 3. Summer visit to St. Alban's Abbey and town. This visit, advertised in last week's issue, is postponed until Oct. 1, to meet the convenience of members wishing to take part.

ERNEST S. GALE } Hon. Secs.
F. T. W. GOLDSMITH }

CHIPS.

The work of sewerage of the village of Bushey, near Watford, has just been commenced. Mr. Urban Smith, of Hertford, is the engineer, and Mr. Jackson is the contractor.

The Lord Mayor of London opened on Friday an eastern wing which has been added to the Marine Hotel at North Berwick. The new wing measures 74ft. by 60ft., having a tower at each corner carried to a height of 90ft. The work was in the hands of the firm of Messrs. J. Watherston and Sons, Edinburgh.

Mr. T. E. Wilford, a clerk of works under the School Board for London, died last week at his residence in Stoke Newington, at the age of 45. For some years he held a similar appointment under the borough surveyor of Leicester, and resigned that post in 1890 for the one he held at the time of his death.

The local board of Todmorden have decided to purchase the undertakings of the three gas companies that supply the district. The terms are 18½ years' purchase on the average of the last three years' profit, or £103,362 10s.

The Government of India have unanimously agreed to present the requisite amount of gun-metal for the equestrian statue of Lord Strathnairn about to be erected at the junction of the Knightsbridge and Brompton-roads. Mr. E. Onslow Ford has been entrusted with the commission for the statue.

The Swansea Harbour Trust have instructed Mr. Abernethy to draw plans for the extension of Prince Dock, at an estimated expense of £100,000.

The foundation stone of a new school of Science and Art for Gravesend and Northfleet was laid on Thursday afternoon in last week by the mayor. The site is on the Ferns Estate, at the south side of St. James's Church.

New schools attached to Conway-road Wesleyan chapel, Cardiff, were opened on Wednesday week. The schools consist of a central hall with 20 classrooms, each seated for 30 scholars, ranged on either side, while at one end are two large rooms, each seating 200 adults or 180 infants. Messrs. Habershon and Fawcner were the architects, and Mr. G. E. Griffin was the contractor. The outlay has been £3,500.

The building of a new police station on the East Moor, Cardiff, was commenced on Monday. The contractor is Mr. T. R. Waterman, of Cardiff.

Trade News.

WAGES MOVEMENTS.

LONDON BUILDING TRADES' FEDERATION.—In connection with this recently organised body, a largely-attended meeting was held on Sunday at Putney, near the bridge. The chair was taken by Mr. Percy. Mr. Verder (secretary of the Federation), Mr. Barnes (chairman of the Executive), and Mr. Stephenson (United Builders' Labourers' Union) advocated the claim of trade unionism and the necessity of all connected with the building trade organising in order to protect themselves. It was pointed out that, since the Federation was started, two months ago, 7,000 new members had joined, bringing up the total membership to 22,000. A resolution calling on all members of the building trade in the district to organise was passed unanimously, and at the close of the meeting a large number of new members were enrolled.

WAGES IN THE EXTENDED LONDON DISTRICT.—With the exception of the strike at Bromley, the whole of the disputes in the suburban building trade, arising out of the men's demand for the advance of ½d. per hour in their wages, in accordance with the compromise agreed to at the Building Trades Conference in June, have been amicably arranged. The men have consequently resumed work. At Bromley the strike continues, and a settlement is not anticipated at present.

ABERDEEN.—The granite workers have made a request for an advance of ½d. per hour on their wages. The Granite Association represent that the trade is good enough at present to warrant such an increase, and in the interests of the Master Builders' Association it is shown that, although trade is fairly brisk, the dull season is approaching. Decision on the matter has been deferred until the societies concerned have discussed the question.

CARDIFF.—The Federated trades concerned in the dispute have agreed to send delegates to meet the employers, and these will be armed with full powers to come to a settlement. The employers will meet each set of delegates representing their own branch of the building trade in succession, and fix the terms of settlement with each branch should they come to an amicable agreement. The first meeting between the employers and the delegates representing one of the branches of the operatives took place yesterday (Thursday). The operative masons are not taking any part whatever in the fresh attempt at a settlement, and the terms which may come to between the employers and the various other branches of the building trade will not affect them.

KILBURN MASONRY.—The builders and hewers having demanded an increase of ½d. per hour, the masters conceded the advance, making the wages at present 9d. per hour.

Mr. Frank Sumner, from the office of the Willesden Local Board, has recently been elected surveyor to the vestry of Bermondsey, to fill the vacancy caused by the resignation of Mr. George Elkington.

At the Roman Catholic church at Chatham a new marble altar and reredos, designed by Mr. F. W. Walters, F.S.A., were consecrated for the Lady Chapel.

At a meeting of the governors of the Royal Albert Hospital at Devonport, held on the 22nd ult., it was unanimously decided to add a new operating theatre and hydraulic lift to the building (which was opened in 1863), at a cost estimated at from £1,700 to £2,000.

Holloway's Pills clear the furred tongue, and act as a wholesome stimulant to the liver, and as a gentle aperient to the bowels. They are the best known antidotes for want of appetite, nausea, flatulency, heartburn, languor, depression, and that apathy so characteristic of chronic derangement of the digestion.

DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLEDTCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent.—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

TENDERS.

* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

ABINGDON.—For new school and community wings at the Convent of Our Lady of Mercy, Abingdon, Berks.
Mr. J. G. West, architect:—

Hutchings	...	£4,458	0	0
Silver and Sons, Maidenhead	...	4,100	0	0
Simmonds, Bros., Reading	...	3,983	0	0
White and Sons, London	...	3,733	0	0
Kingler, Oxford	...	3,694	0	0
Robinson, Wolvercot, Oxford*	...	3,595	0	0
Wilkins and Sons, Oxford	...	3,490	0	0
Wheeler and Sons, Wantage	...	3,195	0	0
Sharpe and Sons, Amphilth, Beds	...	3,180	0	0
Buckingham and Son, Winchester	...	3,092	0	0

* Accepted.

ABINGDON.—For new premises, High-street, Abingdon, for Mr. J. C. Clarke:—

Kingler, T., Oxford	...	£1,030	0	0
Wilkins and Sons, Oxford	...	993	0	0
Goodchild, W., Reading (accepted)	...	852	0	0
Buckle, J., Abingdon	...	826	0	0
Wheeler, T., Abingdon	...	815	0	0

ANNESLEY.—For building Wesleyan schools, Annesley, Woodhouse. Mr. J. Wills, F.S.Sc., Derby, architect:—
Munks, J., Hucknall Torkard* ... £703 10 0
* Accepted.

ASHFORD, KENT.—For the erection of new printing works, for Messrs. H. D. and B. Headley (exclusive of machinery). Mr. Henry J. Jeffery, architect. Quantities by the architect:—

Joy, E., Ashford	...	£1,095	0	0
Steddy and Co.,	...	1,030	0	0
Baker, W.,	...	1,000	0	0
Wood, J.,	...	1,000	0	0
Howland, C.,	...	980	0	0
Knock, H. (accepted)	...	965	0	0

All of Ashford.

BECCLES.—For drainage at the Grange (Building) Estate, Beccles, Suffolk. Mr. Arthur Pells, F.S.I., Beccles, surveyor:—

Trew and Co., Ipswich	...	£287	0	0
Allen, Beccles	...	283	16	0
Church, Lowestoft	...	277	19	0
Johnson, Beccles (accepted)	...	260	0	0

(Surveyor's estimate, £277 5s.)

BISHOPSTOKE, HANTS.—For road making, fencing, &c., for the county of Hants Land and Building Society. Mr. William Borough Hill, F.S.I., Southampton, surveyor:—

Paddington, J. F., Bishopstoke	...	£1,200	0	0
Butt, J., (road and fences) Southampton	...	1,062	18	5

views will be distributed into the appropriate places. The corresponding printed matter may go along with them, and the owner's personal sketches and memoranda may be dealt with in the same way. This will occupy a few minutes weekly, but it will save hours of searching at some future time—a time, in all probability, when hours can ill be spared.

Fewer portfolios will serve for the next great division—that of “Materials,” and these will be occupied more by written and printed matter than by views. Case 1, for Concrete, may contain notes on the different substances it is composed of, and the various modes of concrete building. Case 2 may hold information about Mortar and Cement, without which the modern builder can do but little. Case 3 will be devoted to Stone. It may contain particulars of the prices, weights, and qualities of the various kinds; documents showing the pressure required to crush each kind; memoranda of the best way to recognise the bed, and cautions about the faults to which different varieties are most liable. The architect who goes about with his eyes open will be likely to add to these observations of his own as to the way in which stone from various quarries has stood the weather, both in ancient and modern buildings, and addresses of quarry-owners, which he may find it troublesome to obtain just when he wants them. Similar information will be desirable on the subject of Bricks, in case 4. The colour of different bricks will, of course, be noted, and the way in which the weather affects both colour and substance. Case 6 may be devoted to Terracotta. Case 7 will be the place for notes on Marble and Granite, in which, as in No. 3, the strength, colour, and locality will be carefully stated.

Timber, whether oak, fir, ash, mahogany, or anything else, will next have its own portfolio. A yearly list of the brands, which may be obtained from the journal of the trade, will be very useful. Tables of the strength of various woods to resist pressure and tension, and of their stiffness against cross-strain, should not be omitted; and information about the tricks and manners of the less familiar varieties may, on some occasions, prove very serviceable. Why, for instance, larch, in spite of its agreeable colour, is hardly used for anything but hedge-carpentry; and why satinwood can only be safely employed as a veneer, are bits of information which might chance to save an architect from vexatious mistakes. Slates will occupy case 8, and Tiles case 9 of this division. Memoranda of colour, price, and locality, and particularly of durability, will be amongst the chief things to preserve in each collection. No. 10 will be the portfolio for Iron and Steel; and besides notes on quality, it will contain the sections, weights, and strengths of rolled joists. Lead and Zinc will fill case 11, and Brass and Other Metals case 12. Plaster, including fibrous plaster and similar compositions, will find its home in case 13, and with it will naturally go notes about metallic lathing and similar appliances. Portfolio 14 will deal with Glass; 15 with Paint and Varnish; and 16 with the inevitable Sundries. As a supplement to the Division of “Materials,” it is very desirable to have a few shallow drawers, in which samples can be placed. Whole bricks and tiles, it is true, are too bulky to be preserved for comparison in this way. But fragments of them, large enough to show the colour and the quality, can easily be kept, while samples of marble and of various tints of antique and other superior glass are almost indispensable.

“Construction,” which is the third division, will perhaps be more rapidly filled by the junior architect than by the very experienced one. The man who is beginning practice will find something to learn from most constructional drawings. With

advancing years, he will have much of this knowledge at his fingers' ends, and will only care to preserve memoranda of the unusual or the peculiarly skilful. These may be classed under eight or nine heads, as follows: 1, Earthworks and Foundations; 2, Walls, Piers, and Buttresses; 3, Arches and Vaults; 4, Domes; 5, Wooden Trusses; 6, Iron and Steel Trusses; 7, Fireproof Floors; 8, Scaffolding and Shoring; and, 9, Sundries. This division is only meant for information about leading structural features, leaving the subordinate ones to be arranged further on. Thus, it deals with carpentry, but not with joinery; with iron roofs and trusses, but not with iron casements, railings, or ironmongery. It might at first seem well to keep a separate portfolio for theoretical mechanics, and for the rules by which strains, thrusts, &c., are calculated; but it will probably be more convenient to assort these according to the forms of construction which they pertain to. Papers on the forces to be allowed for in wooden roofs will therefore be collected in case 5, those on the thrust of domes in case 4, and so on.

“Details” come next and form the fourth division. Down to this point all architects will find themselves collecting pretty much the same subjects. They all use, more or less, the same materials; they all need to know something of the same modes of construction, and they may all be called on to design buildings of one or another class out of the forty in our list. But in the matter of details this hardly holds good. Few private libraries could contain the multitude of details appropriate to all these various classes of work. Either by necessity, or by choice, most architects are, to some extent, specialists. They need to know something about all kinds of building, and everything about one or two kinds, and it is the details of the one or two kinds which intimately concern himself, which each member of the profession will naturally aim at getting together. We may give the following as an actual example of the way in which detail drawings have sorted themselves in a practice consisting mainly of a church, school, and house building:—Portfolio 1, Domestic Joinery; 2, Staircases; 3, Balusters; 4, Doors and Framings; 5, Plaster Details, Ceilings, &c.; 6, Fireplaces and Mantels; 7, Chimneys; 8, Dormers; 9, Ironmongery; 10, Furniture; 11, Gas-fittings; 12, Piers, Capitals, and Bases; 13, Arcades; 14, Doorways; 15, Mouldings; 16, Buttresses and Pinnacles; 17, Tracery; 18, Turrets; 19, *Flèches*; 20, Finials and Crestings; 21, Wrought Metal-work; 22, Cast Metal-work; 23, Carving; 24, Studies from Nature; 25, Flat Ornament; 26, Coloured Decoration; 27, Colour-patterns; 28, Floors (Mosaic, Tile, Incised, and Parquet); 29, Pattern Glazing and Grisaille; 30, Glazing with Figure-subjects; 31, Church Fittings; 32, School Fittings; 33, Pulpits; 34, Fonts; 35, Organs; 36, Screens; 37, Bench Ends; 38, Gates and Fences; 39, Sundries. In this way the architect can classify the details which he is most frequently concerned with. Drawings of existing work, whether old or new, will be added, as they arrive, to the collections they pertain to. Amongst these, in the proper places, the owner may put the details of his own buildings. Years after such drawings have been worked from, they have much to teach, especially to their originator and designer. Here he will note that he failed—there, again, that to some extent he succeeded. In one place, perhaps, he found his details, when worked from, too small and delicate; in another, too bold and coarse. All these things he notes on the drawings, after being impressed by them at the building, in the hope of doing better next time; and now and then, perhaps, he sees in one of his earlier ideas the germ of something which might have beauty and freshness. In this way the man who means to make

progress is for ever criticising and correcting what he has done; and by the sort of arrangement this article is meant to suggest, this criticism and correction become so easy as to be almost self-acting.

To the architect proper, “professional practice” may be the least attractive division of the five. But it is none the less indispensable. Everybody, in going through life, has to do a share, and sometimes a very large share, of drudgery, and architects may congratulate themselves that the drudgery, in their case, is relieved by so much that is agreeable. The portfolios in this division may begin with the Acts of Parliament and local regulations. These last, in a practice which includes many provincial towns, will soon increase till they form a little library of their own. Except when one's work happens to be immediately affected by them, they form dreary reading; yet there is one way of looking at them which suggests curious reflections.

If we compare the local regulations of various towns, it is strange to see how widely they differ. In one place, all that the inhabitants seem to be afraid of is fire. They scarcely trouble about drains and sanitary matters. To die peaceably in their beds does not alarm them, but they strongly object to have their houses burnt over their heads. In another place, equally crowded, fire seems to be looked upon as a very trifling evil. Sanitation is everything, and there is little care taken to avoid a wholesale conflagration. So it is in other matters. One might suppose that nearly the same precautions against well-known dangers would be required all over the kingdom. But, whether required or not, the law does not insist on them everywhere. It insists on one thing here and another thing there. There is a popular demand for building regulations, and as long as people get rules and orders of some kind, they seem to be satisfied. It is the pleasure of being controlled, apparently, that they wish for, and whether the control does much good or little, seems to be only a secondary question with them.

“Professional Practice” may go on in portfolio 2 to include law reports relating to buildings, to architects' charges, and other such matters. Portfolio 3 may contain Conditions of Contract, Forms of Agreement, &c. No. 4 may be occupied with information about Light and Air cases, No. 5 with Dilapidations, No. 6 with Drains and Sewers, No. 7 with Ventilation, No. 8 with Heating, and No. 9 with Road-making and the Laying-out of Estates. No. 10 will contain the sundries which cannot be brought under any of the previous heads. The five main divisions will thus comprise altogether about 115 cases. But a reference library of detached articles, drawings, and memoranda may very well be begun with only two or three dozen portfolios. If it is found useful they will increase in number, and may finally constitute the parts of a much more elaborate scheme than the one which we have now attempted to sketch out.

THE OWNERSHIP AND RETURN OF DRAWINGS.

THE question of the ownership of drawings made by the architect has been by this time pretty well discussed, and the obligation of the architect to hand them over to the client should he claim them has been, at least legally, established—the custom of the profession notwithstanding. Yet there are many in practice who seem to be unwilling to abide by the decisions, who either refuse to deliver up the drawings, or do so with a bad grace. But there is another question often quite as perplexing and confusing, and even of more frequent occurrence, and that is the property of drawings furnished to builders, tradesmen, clerks of works, and

others requiring them. Is the builder justified in refusing to return the drawings or tracings after the work has been carried out? And what is his legal right in objecting to give them up? With regard to the first question, the client's right to the possession of the drawings, it is unnecessary to state again the dictum of the Lord Chief Baron of the Court of Exchequer, concurred in by the late Baron Bramwell and others in the case of "*Ebdy v. McGowan*," which was tried in 1870. That dictum declared that if there was no provision to retain plans and specifications, the architect had no right to them. The custom or usage amongst architects was, it was thought, unreasonable, if it existed, which Baron Bramwell thought was impossible, and, in fact, said was "perfectly suicidal." His Lordship, in fact, said such "a usage cut its own throat with its own absurdity," and contended there was no such usage. The claim made by the late Mr. Ayrton against the late E. M. Barry, R.A., for the drawings of the Houses of Parliament prepared by himself and his father, may be remembered also as one that went right against the architectural conscience. In the year 1871 the Council of the Institute obtained the opinion of two lawyers—Mr. Justice Manisty and Lord Justice Bowen—on certain questions drawn up by a committee, and this opinion clearly affirmed the principle of the above decisions. Mr. Wyatt Papworth, in a recent number of the R.I.B.A. *Journal*, publishes this opinion, to which we now refer. In answer to questions 1 and 2, the opinion was "that in the absence of express provision to the contrary, all plans and drawings which are prepared by an architect in the ordinary course of, and as incidental to, his employment as architect, are paid for by and belong to the employer both where the projected building is and where it is not carried out." The italics are ours. As to the question of alleged custom to retain plans, the opinion is equally important. It declared that such custom "seems to us to amount to no more than a very general practice to that effect," and falls "very far short of evidence sufficient to prove a custom binding upon all persons who employ an architect in the ordinary way," and they express a strong opinion that no such custom could be established. It is further given as their opinion that supplementary detail drawings stand upon the same footing, the architect being paid for making all such drawings as are reasonably necessary. From a legal point of view, therefore, the decisions have been against architects retaining their plans and drawings.

As to the second question, whether the builder has a right to retain drawings or tracings supplied to him by the architect for use in carrying out the building, there appears to be a difficulty, as builders have sometimes refused to part with these documents, contending they have been furnished for their own use, and that they form a part of the contract. We may suppose a case. An architect wishes to examine for some purpose the copy of plan supplied to the builder, it may be to compare with his original in case of a misunderstanding, and he requests a return of the plan, or he wishes to give the builder another plan. The builder refuses, saying the copy he has represents the work he undertook to perform. A similar refusal may be made by a manufacturer or special artist to return the designs or detail drawings sent to him after the execution of the work. Both builder and manufacturer may reply that the drawings supplied are their own, or, at any rate, the employers have more right to them. The law in these cases is doubtful, though the ruling of the courts certainly imply that all drawings, whether original or copies, belong to the employer. An architect generally makes a duplicate set

of drawings: one of these, the original contract set, he keeps himself as evidence of the contract, as showing what work was agreed to when the contract was signed. Sometimes when a board is one of the contracting parties, the solicitor or clerk is the custodian, but the practice is not a common one. These drawings and specifications which form part of the contract must certainly be preserved intact, so that neither party may alter or tamper with them; they are retained for reference and for safe keeping. Copies or tracings of these drawings are next made, one set for the builder, another for the clerk of works, and sometimes a third for the quantity surveyor, or the latter supplies the builder with a set of tracings. Various detail drawings and designs are made for sub-contractors and special artists engaged. After the execution of the works these several tracings and details ought properly to be returned to the architect; but in many instances they are retained in the possession of the several parties, and if application is made for them, they are refused, or the answer is they are worn out or lost. The architect has only one resource open—to summons the party; but this is seldom resorted to. Now the effect of this refusal to yield up the drawings and details after the completion of the work is that the plans and designs may be used in other works. Clerks of works and surveyors, too, have sometimes been unscrupulous enough to use the designs and details, or to profit by them in some way. We know of one clerk of works who was in the habit of offering old working drawings to those who were willing to purchase them, and every practitioner knows how often his details, especially mouldings, are re-used. Manufacturers also keep a stock of designs by them, and frequently show them to other customers as testimonials of their employment by well-known architects. Again, a builder who keeps his drawings may perchance find them of value at some future day, when alterations or additions have to be made; their possession may at least be of profit to him.

The right of property in their designs and details can be retained by architects if they provide for it in the contract conditions, or make a special proviso in some other way. No merely formal affirmations of the profession have the slightest effect in law. For example, the Institute, in a resolution passed by its Council, affirmed that drawings furnished to builders and others are only supplied for the purpose of executing the work, and are not in any sense the property of the builder, and he ought in all cases to return the drawings and any copies of the same he had made for his own convenience. As an expression of opinion, only for the guidance of their own members, such a resolution may be useful, as in the other professional declarations made as to fees, &c.; but they are absolutely powerless to bind the builder or the client, unless he agrees to the condition. The same may be said of trade-union rules, which are not binding on the employer. No body of professional men can make laws for other people; but they can make agreements with their clients. Several architects are in the habit of writing on every tracing or drawing that leaves their offices: "This drawing is the property of the architect, and is to be returned to him on the completion of the works." If words to this effect were written or printed and affixed to every tracing and drawing which left the office the difficulty to which we have referred would be obviated. Builders would begin to learn the conditions under which they received drawings. As to the return of copies made by builders themselves, of course very little can be done, except to rely upon the good faith of the recipient. Clients often require to see plans if they contemplate making alterations or to

discover the course of drains, and there is no doubt the architect may be legally called upon to permit his client access to them. The question has, however, never been authoritatively determined.

All the trouble that has arisen between employers and architects in respect to the ownership of drawings is the result of the very strong and mistaken idea entertained by the public that the architect's plans and designs are the goods which are purchased by the commission. Instead of being regarded as merely the instruments or means employed by the architect in carrying out the building, they are looked upon as the actual work or service rendered. The profession have to try and eradicate this notion of their function, to endeavour to show that the paper design or plans are equivalent to the written prescription of the physician, and nothing more. The physician is consulted to cure a malady or restore health, and whatever means he uses to accomplish his purpose is immaterial to the patient; so the architect is consulted to design and carry into execution a building, and to this end he is obliged to represent his ideas on paper, in much the same way as the physician is obliged to write a prescription of the treatment or drugs required. Both have to use certain means or instruments. It is true a prescription is sometimes lent or given to a friend; but such a practice is, to say the least, dangerous, and the lender must have a fool for a patient. The plans of a house prepared by an architect are, similarly, like the prescriptions prepared under special conditions and circumstances. The professional adviser in each case has a substantial reason for repudiating any such transference or re-use of his opinion, and on this ground alone the architect is justified in requiring the return of plans which may be re-used to his disadvantage. A prescription is a two-edged sword, and may kill or cure, and therefore its value is only to its owner; but the architect's design is regarded in the light of a valuable commodity that is paid for, and may be bartered or lent whenever occasion offers.

The retention of drawings and the return of those furnished to builders and others must be made a matter of special contract if the profession desire to protect their interest and to prevent the practice of making use of designs which are intended for only certain positions and purposes. Even in the case of perspective views, which are not prepared for contract use, an understanding is necessary to avoid after-disagreement.

INCOMBUSTIBLE CONSTRUCTION.

WITH all our boasted advancement in the science of construction, it cannot be said that we have done much to render our buildings less inflammable. On the contrary, though the Building Acts of the Metropolis have been framed mainly to reduce the risks of fire, they have practically only insured a fire-resisting case of brick or stone, leaving the interior—a mass of combustible material—at the mercy of builders without any efficient safeguards. The present Act, as far as the Metropolis is concerned, has not touched the vital points to be observed in insuring the safety of those who work in, or inhabit, buildings against the untiring foe which is always present in one form or another, and which is ever ready when not under control to become supreme master. Everything that can be done to check the beginning of fire ought to be adopted. One would expect also that all means of escape and communication between one part of a large building and another would be protected by resisting and incombustible materials; but, strange to say, these are the very portions of most buildings, dwellings

especially, which are of the most combustible and temporary character. Internal partitions, those dividing passages and corridors from rooms, are often of wood, the staircase which ascends to the top story is of wood, and, worst of all, they are hollow-built, match-boarded construction which invites ignition and rapid combustion. Massive and solid timbering has resisted the spread of flames; but the modern casing and hollow partition have become a too ready prey, by reason of the currents of air which can penetrate them so easily. In short, it is not only because our modern buildings are constructed of wood, but because of the manner they are constructed, that we so repeatedly have to chronicle cases of outbreak of an alarming and heartrending kind. Two fires that occurred on Monday last, one in Montague-place, Bedford-square, and the other in the neighbourhood of Commercial-road East, draw the attention again to the extreme danger of unprotected and unsafe staircases in houses of several stories. In the Montague-place disaster the premises were used as a boarding-house, and were, in fact, two houses converted into one, having no fewer than 43 inmates at the time of the outbreak. The fire broke out at the back of the ground floor, and soon involved the stone staircase ascending from it to the second floor. One or two hairbreadth escapes are recorded, owing to the sudden and early collapse of the upper part of the stone staircase, which had been exposed to the heat of the flames a few moments, thus cutting off the descent of three ladies who were rescued at the peril of their lives by the courage of the firemen. In the second instance the three-story house was tenanted by four families. The flames originated in the ground floor front room, and the wooden staircase taking fire cut off the escape of those who were asleep in the upper floors, who had to jump from the windows at the imminent peril of their lives.

We have here the record of two fires on the same day in which the staircases were so quickly involved that escape by them was impossible. And, what is necessary to remark, one was of stone, the other of wood. No doubt the builders of the well and substantially-constructed houses in Bloomsbury erected stone staircases under a sense of the greater security they afforded, and this is still the opinion of many people who imagine a stone staircase insures at least a safe retreat in case of fire. This belief has been shaken unhappily only too often. The treacherousness of limestone, such as Portland, to suddenly give way under heat is known to all firemen, and Sir E. M. Shaw has warned the public of the danger and uncertainty of stone when exposed to heat. A wooden staircase gives often a timely warning by the crackling and smoke; but a stone one does not. It flies to pieces and calcines into powder, as ample evidences have shown us in the notable case of the new front of Foster's premises in Cheapside, a few years ago. Still architects use stone in good houses in preference to other materials. Have not all our large public buildings and private mansions stone staircases of the same kind as that in Montague-place? And would it be tolerable to introduce anything else but real stone? The answer to these questions is that natural stone should be only used in staircases round which incombustible walls and floors are employed, and not when timber forms a large part of the interior construction. With these combustible materials some form of concrete stairs ought to be used, incasing walls of brick being the only safe construction in connection with buildings of fireproof material.

The wooden staircase constructed of treads and risers upon strings of the close or bracket form, are always dangerous, more particularly when they are continuous and have an open well, which becomes a veritable

furnace-shaft in case of fire. Solid wooden steps resting upon brick walls would resist fire for a considerable time, and so would hollow stairs filled in with concrete or asbestos—a plan that ought to be followed in every building of more than two stories.

The frequent calamitous fires due to the inadequate rules of the Building Acts in London in these particulars ought to lead to a revision of the sections applying to fireproof construction. The present system of hollow floors, partitions, and stairs ought to be abolished, and a plan of filling in solid with fireproof material be made to take its place, in all buildings of several stories used as dwelling-houses, shops, and warehouses. The proposed amendments to the London Building Law (Consolidation) Bill provide for an opening or trap-door on the roof as a means of escape, and that every staircase for the use of the public shall be supported and inclosed by brick walls not less than 9in. thick; section 22 provides that every building of more than 125,000c.ft. used as a dwelling for separate families shall have stairs, lobbies, and corridors of stone or other fireproof material. These rules do not apply to the thousands of old houses converted into boarding-houses, or to ordinary dwelling-houses of smaller capacity let for lodgings, such as many in Bloomsbury and other parts of London. The wooden partition forms a large part of the interior of many of these; bedrooms have been divided by match-boarded partitions and there is no means of escape. The modern dwelling-house is all wooden partitions; the stairs are constructed of the lightest deal, and the lower flights are encased on the lower story, and inclosed by a matchboarded spandrel. What is to prevent a fire in a closet under the stairs igniting the staircase? Again, the hollow wooden-studded partition is on one side of the staircase, and is carried up to the top floor. A fire occurs in a lower room by the upsetting of a lamp, the partition becomes ignited, and the draught through the studs between the plastering communicates directly with the floor above, which is soon involved—thus the fire spreads from floor to floor. Now this communication may be cut off by filling-in the partitions with a fireproof material, or by filling-in the space of each above and below each floor, so as to prevent draught and check the spread of the flames to the flooring. As at present constructed, the open partition forms a communicating flue of the greatest danger. There is nothing in the Metropolitan Building Act to compel the builder to provide any check. In New York the recent regulations require not only stairs and landings to be built of incombustible materials, but that no woodwork is to be used in any of the partitions, furrings, or ceilings, the door and window-frames and casings being filled solid at the back with fireproof material. Any revisions of the Building Act that may be made ought certainly to prohibit hollow wooden construction, and to provide some checks to the rapid spread of fire, and to this end attention should be drawn to the absolute necessity of making partitions and open-cased structures, like stairs, solid by the use of suitable material as a filling, on the principle that wherever there is a passage for air there is the risk of flame.

STABILITY OF WALLS ON SOILS.—V.

Equilibrium as a Principle of Stability.

IN the textbooks on physics three different states of equilibrium are defined depending on the relative positions of the centre of gravity and the centre of support, or on the property of rigidity combined with a favourable disposition of the form of the rolling or bearing surface of the object to assume rest or motion. The centre of gravity of a body or mass tends incessantly to occupy the lowest possible position, and hence the distinction, "stable," "unstable," and

"neutral" equilibriums are made in relation to the modes by which stability is attained or affected. In "stable" equilibrium the body always tends to return to its first position after the equilibrium has been disturbed. The centre of gravity may be either above or below the centre of support. Ordinarily architectural buildings do not come under this class, for although tall chimneys rock or sway with fierce winds, due to elasticity of the upper masonry, the disturbance of the centre of gravity thereby is unappreciable. "Unstable" equilibrium is the state existing when after a slight disturbance the body tends to depart still more from its original position; the centre of gravity is vertically above the centre of support. Buildings supported on compressible soils would act in this manner. "Neutral" equilibrium has the centre of gravity above the point of support, such as a globe or a cone lying on its side on a level plane. A familiar illustration of the three kinds of equilibrium is a cone placed on a horizontal plane: 1, on its base, it is in "stable" equilibrium; 2, balanced on its apex, it is in "unstable" equilibrium; 3, placed on its side, it is in "neutral" equilibrium.

The conditions on which equilibrium depend are—1. The lines of action of all the forces must have their resultants in the same line. 2. There must be equal forces acting in opposite directions along this common line of action—i.e., action and reaction are equal, and in opposite directions. 3. The points of application of force may be anywhere along the common line of action, and therefore the sums of any number of forces in the same line of action in opposite directions must be equal.

In structural practice if this line of action is represented by several stories of columns in one continuous vertical line, the loads of the several floors transmitted by the girders should be applied or imposed so as to act along the continuous axis of the columns. This frequently can only be effected by so skillfully arranging the points of support centrally that the girder loads on one side will be balanced by having corresponding girder loads on the opposite side, otherwise there would be eccentric loading that induces excessive cross strains, which, to meet adequately, would be at variance with economy.

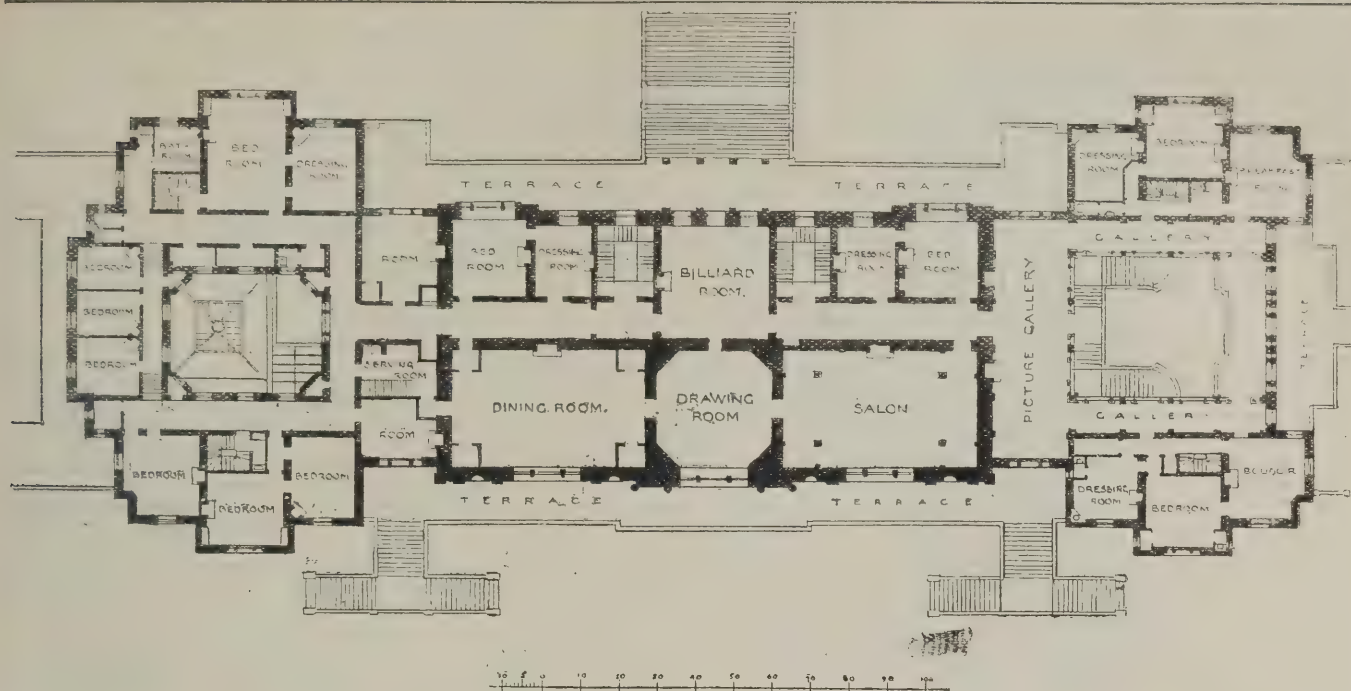

Conditions of Equilibrium of Forces.—The principles of equilibrium imply that all forces causing or tending to produce disturbance or change of position, or deformation of parts, or of the whole, are fully and effectually resisted by a corresponding system of opposing forces, whether effected by ample dimensions of parts, adequacy of their disposition, or massiveness of materials, and of the medium or matter producing resistance. The action of force in tending to produce displacements or deformation depends upon (1) the favourable position of the point of application of the force to create static couples; (2) on the favourable direction in which its action tends to produce disturbance by enlarging the moment of the couples; (3) upon its amount or magnitude, or surplus magnitude, in relation to that of the opposing forces, or moments of matter.

It is, therefore, the duty of the designer to effectually resist all these displacing forces, and his skill is displayed in effecting this in the most direct and economical manner, by the most adaptable scientific system of concentrating the loads and controlling the resultant forces so as to produce direct vertical action, and by making the supporting area concentric with the axis of loading.

Equilibrium in Structures.—Structures of all kinds are incessantly under the action of two or more opposing forces, or systems of forces, tending to cause motion or displacement of the whole or of parts of the structure in different directions, according to that of the surplus force.

The prime cause of motion or displacement in foundations is in neglecting to place the centre of action of opposing parallel forces directly opposite to each other, or in the same line of action, whereby a statical "couple" is constituted. The measure of the force of this couple is the magnitude of the active force. The moment of the couple is the product of the force by the length of its leverage arm, or the distance between the forces perpendicular to their lines of action.

The principal forces involved are those arising from the action of gravity, which is ever present, and the resisting strength of the constructive materials involved, the supporting power of the soil, &c.

GOSFORD HOUSE, N.B.: PLAN OF FIRST FLOOR.

Stability.—The stability of a structure depends on the equilibrium of its parts and masses, on its centre of gravity being effectually supported. This support may be either by direct vertical interposition of solid materials, or by means of abutting support, which may be obtained by the interposition of beams, girders, cantilevers, or other sustaining transverse structure, which transfers the weight of the superstructure to the abutments or imposts, piers, &c.

In all cases, the centre of gravity must fall sufficiently far within the edges of the base, so that the pressures will not rupture the materials of the base near its edges.

In all pressures that are not vertical there will be a vertical component in its action upon the structure. Thus, though the normal action of wind is horizontal, yet in its tending to overturn the structure, it produces a vertical component on the foundations which must be provided against. The differences in the distance of the common fulcrum from the vertical and horizontal centres of application of pressures,—say that of wind upon the geometrical centre of a high tower, and its resultant action upon the foundations and upon the underlying soil, determine the relative intensities of the pressures.

The resultant of an equally-distributed pressure like that of wind is assumed to act at, or near, the geometrical centre of the surface of exposure, and its leverage of action is the height of this point above the footing base; the leverage of resistance is half the width of the foundation base.

Conditions of Equilibrium of Buildings upon Foundation Soils.—The conditions which regulate the static equilibrium of buildings upon their foundation soils depend—1. Upon there being a safe reserve balance established between the gross load imposed on the soil by the building as a whole, and the safe sustaining power of the soil upon which it is imposed. This reserve is usually obtained by using a factor of safety of 3 to 5, according to the character of the building, &c. 2. It also depends on the subdivisions of the structure balancing each other, by a consistent distribution of the parts, and of similarity of forms of adjacent supporting bases. 3. That the forces and resistances exerted by and upon each part of the structure shall balance each other, so that horizontal or oblique thrust shall not be exerted unrestrictedly against the foundation soil base, such as when the resultant line of thrust of an arch lies outside the base of an abutment tending to overturn it by depressing its heel, and that the resultant of the imposed forces of the structure shall be equal and directly opposite to the resultant of the reactions of the sustaining forces of its foundations.

Conditions of Permanence of Stability.—The conditions which will insure permanence of stability are very important, and may be regarded in a twofold aspect—1. Sufficiency of the design and of the details throughout, and likewise of

the workmanship. 2. The durability and appropriateness of the materials in their proper places, and adequacy of protection of the less permanent materials.

Note.—It is implied in 1 that there is the power of a skilful determination and economical selection of the appropriate materials—i.e., those which are best adapted by their special or general properties for each part of, and position in, a building; and it is implied in 2 that there is the practical qualification of personally judging of their precise grades and qualities, not so much by their trade marks or commercial brands, as by personally recognising the absolute fitness in all their physical or chemical peculiarities to best serve their precise purpose in the structure.

For the latter purpose in relation to building stone, Prof. Beare's contribution, *BUILDING NEWS*, p. 628, Vol. LXII., furnishes eminently useful information: (1) In regard to the expansion and contraction of stone in masonry, due to changes of temperature, and the means thereby afforded of calculating the abnormal stresses thereby induced in piers, lintels, and other parts when they are made slender, and require a judicious reserve of strength. 2. Also information in regard to the absorptive power of different kinds of stone as an indication of their weathering qualities, and their liability to the solvent action of rain, and the destructive action of frost, and the resulting loss of strength by both of these agencies.

(To be continued.)

GOSFORD HOUSE, N.B.

[WITH LITHOGRAPHIC ILLUSTRATIONS.]

WE give Mr. William Young's Royal Academy drawing of this mansion, which was completed for the Earl of Wemyss a short time ago. A previous "new" mansion-house, designed by the brothers Adam, was finished in 1803, and the valuable collection of pictures belonging to the house of Wemyss was transferred from the old house—now demolished—to that building. Soon after the pictures had been hung in their new quarters, however, an apprehension arose that the building was damp, and the collection was removed again to the old house, and the new mansion, partially demolished, remained tenantless. It is this building which Lord Wemyss has restored into a palatial mansion. We give plans of the enlarged house with the view. In addition to the internal reconstruction of the central portion of the original building which remained, wings have been added on the north and south ends. At the south end of the building, which, including the wings, is in length 341ft., is an entrance courtyard inclosed by an ashlar-pannelled and pilastered stone wall, corresponding with the architecture of the house, and there is a similar courtyard on the north side,

known as the kitchen courtyard. The ground-floor story is of rustic stonework, and on the west and east, to the sea and garden fronts of the original building, is an arcading of a similar character extending about 10ft. from the old walls, and forming a piazza on the ground level, and on the principal floor a broad terrace connecting the two wings. From this terrace, to which the principal rooms open, charming views are obtained westward of the Firth of Forth as far as the Forth Bridge, while on the east side there are delightful vistas of the gardens and ponds which are a feature of Gosford policies. In the centre of the latter front is a grand flight of stairs, 38ft. in length, giving access to the gardens. The exterior of the sea-front of the central building is treated as a Corinthian order, extending the whole length of the wall above the terraces, with double pilasters at the ends, and engaged columns in the centre. Between are large arched windows, with a minor ordnance of the Ionic order. In the centre is a pediment, over which, springing from an octagonal base, rises a dome, the outlines of which must be familiar to all who have enjoyed the view of Aberlady Bay from the Calton Hill, of Edinburgh. The Ionic order is carried through the new wings, which have broken and picturesque outline, and the design adopted is such as to give to the whole composition a pyramidal form. The entrance is at the southern end of the house from the main avenue, and through a court inclosed by ashlar walls, designed in character with the architecture of the house. Passing through an outer hall—in design quiet and simple—entrance is obtained to the magnificent staircase hall, which is the feature of the interior of the mansion-house. The lower story of the hall is surrounded by solid walls, panelled in Caen stone and alabaster—broken only by three doorways with alabaster architraves and over-doors, and two niches for life-sized figures. On this wall for a base rises an arcading of alabaster and Caen stone, which extends around the four sides of the first floor. Facing the entrance door is an oval baluster arch, resting on similar clustered columns and pilasters. A double marble staircase, starting on each side of the hall, is carried over this arch—in treatment not unlike the Rialto Arch at Venice—and meets in the centre, while inside the arch is a fine Italian chimney-piece in Istrian stone. The balustrade which extends up the staircase and continues round the first floor is of alabaster, with base and capping in Caen stone. On the ground floor the hall is 38ft. by 48ft., but on the first floor it opens up by the arcading—behind which extends a corridor overlooking the hall—to 56ft. by 70ft., with a height of 45ft. from the floor to the centre of the dome. This arcading is formed by a Corinthian main order in Caen stone 20ft. high, each side being divided by pilasters into four bays, and the ends into three bays. Each

bay is again subdivided by a minor ordinance of the Ionic order into three, by a Venetian arch and side openings formed with alabaster columns, pilasters, archivolt, and inlaid alabaster spandrels. A rich entablature in Caen stone completes the arcade, and above this springs a bold cove panelled and enriched in canvas plaster work. The ceiling is thence brought into the form of a circular dome, all in enriched canvas plaster. The floor of the hall is of veined marble corresponding with the steps of the stairs, laid in geometrical patterns and surrounded by a border of rouge jasper marble. By the marble staircase is reached the principal floor (see plan on the preceding page), which contains the whole of the reception and living rooms, as well as the family bedrooms and most of the guests' rooms. The picture-gallery, which is first entered, is 63ft. long by 20ft. wide, and has a beautiful canvas plaster ceiling and three cupola lights. At each end of it there is an entrance to the corridor running round the staircase hall and overlooking it. From this corridor access is obtained to Lord and Lady Wemyss' apartments and other rooms, the south wing having been planned so as to form in itself a complete little house. From the picture gallery, again, a doorway opens into the corridor which extends from end to end of the central building and connects the wings. The sea or west front of this part of the house is occupied by three magnificent rooms, two stories in height—viz., the *salon* or library, 50ft. by 30ft.; octagonal drawing-room, 30ft. by 30ft.; and the dining-room, 50ft. by 30ft., and each 40ft. high. On the east side of the central position are two floors of bedrooms, and the north wing is also entirely devoted to bedroom accommodation. In the centre of the wing is an open court, the ground floor of which forms the kitchen, the remaining part of the wing being devoted to domestic offices.

A SANITARY CRUSADE THROUGH THE EAST AND AUSTRALASIA.—II.

(Continued from page 312.)

LEAVING the Malay Peninsula, Mr. Boyle proceeded to Siam, Bangkok—the capital, dubbed the “Venice of the East,” being the first place visited. This city, which has a population of about 400,000, a large proportion of whom are Chinese, is an exceedingly unhealthy place, where cholera, which is never absent, carries off thousands of the inhabitants annually, to say nothing of the victims of small-pox and other fevers and diseases which make Bangkok their home.

The foul water which the people drink is chiefly responsible for this terrible mortality, the city being intersected by canals or creeks which run into the river Menam, and which are in a partially stagnant state. The excreta and all the filth and refuse of the town are deposited in these creeks, the water of which the inhabitants use for drinking and cooking purposes, and which is in such an impure state, being practically nothing but liquid sewage, that the stench arising from it is quite overpowering. The water of the Menam is also very poisonous, and contains poisonous fish and reptiles to such an extent that it is positively injurious to even take a bath in water drawn from the river.

Mr. Boyle has seen several cholera and small-pox epidemics in the East, and as instances of the utter want of precaution and indifference of the people, he has observed natives stricken with the cholera lying in the streets totally uncared for, and the cholera carts followed by numbers of children, who, from their laughter, seemed to think the ghastly work highly amusing. It is also a common thing, especially in China, for small-pox patients to walk about the town with the disease full upon them, and as the streets are usually narrow and crowded, it is next to impossible to avoid contact with them.

The mode of disposing of the dead in Bangkok is of a somewhat rough-and-ready description. Cremation is the method adopted. When a person dies the body is conveyed to a burning Wat or temple, where for a small sum sufficient firewood is provided to consume it; but when it happens that the relatives have not got the required amount the body is simply deposited on the ground and left there. Hundreds of bodies may be seen at any time in the temple inclosure lying about in heaps in every stage of decomposition and decay, and from which a most sickening odour arises. As many are the bodies of

persons who have died of cholera, small-pox, and other infectious diseases, it will be readily understood that these pest-spots form an important factor in the death-rate of the city. In striking contrast to this disgraceful state of affairs, the palace of the king, standing within its fortified inclosure, is a perfect model of cleanliness and order, and the royal Wats or temples are amongst the finest in the East, and kept in perfect preservation. To see these temples alone would well repay a visit to Bangkok, as they are perfect gems of art, and there is nothing like them to be seen anywhere else in the East, not even in India, that country of magnificent temples.

Mr. Boyle made a survey of the palace, and has furnished plans for the application of his system of ventilation to it. One of the largest figures of Buddha in the world is to be seen at Bangkok; it is recumbent, and measures about 170ft. in length by 50ft. at the shoulders, and is inclosed in a magnificent temple. There are a number of very handsome public buildings in Bangkok, built in European styles of architecture, chiefly Italian. There is cable connection with the city, and the telegraph and telephone are in general use; tramcars run in the principal streets, and electric lighting has been introduced.

Two lines of railway are at present in course of construction—one from Bangkok to Paknam, at the mouth of the Menam, a distance of 30 miles; and the other up country to Korat *via* Ayuthia, the ancient capital of Siam. This line will be about 130 miles long, and will be of great value in opening up the country and aiding the progress of civilisation in Siam, which has a mixed population of eight millions; but, like the Chinese, the people are very much opposed to innovations of any kind. During Mr. Boyle's visit, the first sod of the Korat Railway was cut by the King, and a very grand ceremony it was, and a magnificent display of barbaric splendour.

Borneo, which, after Australia, is the largest island in the world—New Guinea ranking third—was the next country visited by Mr. Boyle. It is very sparsely inhabited, the total population being under 3,000,000, the greater part of the country being covered with almost impenetrable jungle. The native Dyaks are a very savage race, their chief recreation being head-hunting, and he who can show the greatest number of heads decorating his hut is considered the greatest man. Mr. Boyle had the privilege of witnessing a party of Dyaks performing their war dance, and a very wild and fantastic scene it was, as the moonlight shone in fitful gleams through the dense jungle growth, lighting up the naked bodies of the savages as they whirled their phrangs or war-swords round their heads and brandished their shields, covered with tufts of human hair, each tuft representing a head, whilst the uncouth sounds from the reed instruments and drums produced an eerie and weird effect that was impressive, though somewhat startling.

The territory of Sarawak, on the north-west coast of Borneo, was acquired from the Sultan of Brunei in 1842 by Sir James Brooke, who assumed the title of Rajah of Sarawak, and which is held by the present Rajah, Sir Chas. Brooke, who has devoted himself to the development of his territory, closely guarding the interests of the natives, whom he will in no way allow to be exploited.

Kuching, the capital, situated on the Sarawak river, about twenty miles from its mouth, is a very handsome little town, containing several fine public buildings, including a very good hospital. The sanitary condition of the town is satisfactory, and it is considered a healthy place for Borneo. Sandakan, the chief trading centre in British North Borneo, has a magnificent harbour, but it cannot be called a healthy place, neither can Labuan, which seems to be gradually going down as a trading centre.

On many of the plantations all sanitary laws, so far as the coolies are concerned, seem to be entirely ignored, the consequences being an enormous sacrifice of human life. The wretched coolies are also treated worse than beasts, the most inadequate provision being made for their accommodation and subsistence, the result being in such a pestilential climate that they die off like flies. Things are at present at very low ebb in North Borneo, and many of the plantations have had to be closed.

From Borneo, Mr. Boyle proceeded to Java, a very beautiful and fertile island, having a population of about 21 millions. Batavia, the capital,

is a well-laid-out town, intersected, as in Holland, with canals, lined on each side with trees. There are several handsome public buildings, including the Government Buildings and the Museum, for the ventilation of which Mr. Boyle has submitted plans. Batavia was long noted for its extreme unhealthiness, cholera carrying off thousands every year. Before the artesian wells were employed, the inhabitants used, for all purposes, the water of the river and canals, which receive, as at Bangkok, the whole of the excreta and refuse of the city. Batavia lies in the midst of swamps and jungles from which arise a poisonous malaria, which has a very injurious effect on the health of the people.

At Tanjong Priok, the landing-place, six miles from Batavia, and connected by rail, the miasma arising from the mangrove swamps is so dense at night, as to completely enshroud the place, and it has a very sickening and disgusting odour. This is the most feverish spot in all Java, and few can stay a night there with impunity, as Mr. Boyle found to his cost, he having contracted the fever there, but which, we are glad to say, he has since entirely got rid of. Railways traverse the principal parts of Java, and the Dutch have shown considerable enterprise and judgment in developing the resources of the country, which, so far as the government of it and its prosperity are concerned, is a model colony.

Leaving Java, Mr. Boyle proceeded to Australia, travelling through Queensland, which has now a population of about 400,000, made up of whites, Chinese, and natives. This colony, it is anticipated, will ultimately develop into one of the richest mineral fields in the world; but at present things are, as is indeed the case over the whole of Australia, rather depressed, though there is a tendency towards an improvement. Brisbane, the capital of Queensland, is a handsome and rising city, beautifully situated on the banks of the Brisbane river, about twenty-five miles from the sea, and has a population of about ninety thousand. It is considered a very healthy town, though hot in the summer, and the pure, dry air is found to be beneficial for pulmonary complaints. It contains a number of remarkably fine buildings, chiefly situated in Queen-street, the principal thoroughfare, some of which are from the designs of Mr. Richard Gaily, the President of the Queensland Institute of Architects, who has paid considerable attention to the important question of ventilation, and has furnished Mr. Boyle with the following valuable report as the result of his experience: “I know of no method equal to Boyle's system, and I am confident that its application to our public buildings would very much improve their ventilation.”

The Vice-President of the Institute, Mr. Henry Hunter, also reports, “I know of no system of ventilation so suitable to our requirements in this part of the world as yours,” which is endorsed by Vice-President Mr. Leslie G. Corrie, who says: “There are no systems of ventilation or ventilators with which I am acquainted which answer our manifold requirements so satisfactorily as do those bearing your name.”

The Houses of Parliament, new Treasury buildings, and the Supreme Courts are very fine specimens of architecture, whilst the Banks and Insurance Offices are equal to any buildings of their kind in London, and are erected to the designs of, amongst other architects, Mr. G. W. Addison, who, writing Mr. Boyle *re* the manufacture of his appliances in Australia, says, “With your world-wide reputation you can almost command the market.” Messrs. Nicholson and Wright, architects, who have several important public buildings at present in hand, for which they have specified the Boyle system, also report, “We are quite convinced that your system of ventilation is the best.”

There is no system of sewerage at present in use in Brisbane, pail-closets being used; but as it is only compulsory to clean them out once a week, where the closet is inside the house, disagreeable smells are occasionally experienced. It is a regrettable fact that leprosy is increasing in certain parts of Queensland to an alarming extent; but stringent measures are being put in force to keep this terrible disease in check and stamp it out, which, if rigidly adhered to, may ultimately prove successful. Messrs. James Campbell and Son, Limited, Brisbane, have been appointed agents for Queensland.

Sydney was the next place visited, and Mr. Boyle was astounded at the progress this city had made since his first visit, seventeen years ago, it being then a quiet, sleepy old town;

KING OF SIAM'S PALACE, BANGKOK.

now it has doubled its size, and was, even though the times are quiet, all life and bustle. The immense and palatial buildings which line the principal streets, George-street and Pitt-street, from end to end, put one very much in mind of Chicago.

The population, including the suburbs, is about 300,000, and it is within the bounds of possibility, from the great strides that it is making, that Sydney, at no distant date, may equal Melbourne itself. Very special attention has been paid to the sanitation of the town, the most improved system of sewerage being in use. The Water and Sewerage Board make it compulsory for every house-drain and soil-pipe to be ventilated with approved ventilators, and Mr. Smail, the engineer to the board, one of the highest sanitary authorities in the colony, has spared no efforts to make Sydney practically realise Dr. Richardson's "Hygeia" or "City of Health." Mr. Smail instituted lengthened experiments with a view to test the exhausting power of the different ventilators submitted, but like the experiments carried out by the Sanitary Institute at Kew, the results were of an inconclusive nature, for though the majority of the ventilators were found to be better exhausts than a plain open pipe, yet when tested against each other in certain situations, conflicting results would be obtained when tried in other positions, though in each case the ventilators were fixed clear of all external obstructions. These tests afford an additional proof that it is impossible to correctly ascertain the comparative exhaustive power of different ventilators, especially when of a small size, by simply placing them on the tops of pipes in certain situations, and testing them with an anemometer or the water test, and they endorse the results which have invariably been obtained from similar experiments carried out at different times in this country. There is at present being practically tried in a suburb of Sydney a system of sewer and drain ventilation perfected by Inspector McKenzie of the Sewerage department, consisting of a series of furnaces which create downward currents into and through the sewers, drains, and soil-pipes, and also consume the sewer gases. It is the most perfect application of this method of sewer ventilation that Mr. Boyle has yet seen, and the result of the experiment will be watched with interest, and if successful it is to be hoped that the mere question of cost will not stand in the way of its adoption, though it must be confessed that this principle where tried in England has never given satisfactory results.

One of the most imposing structures in Sydney is the new Australia Hotel, erected to the designs of Mr. G. Allan Mansfield, F.R.I.B.A., at a cost of a quarter of a million sterling. It is certainly

one of the finest hotels in the world, and contains all the latest sanitary improvements, including the air-pump ventilators, respecting which Mr. Mansfield writes Mr. Boyle: "The efficacy of the system of ventilation you have adopted is so well known that comment would be superfluous." The Municipal Buildings and the Centennial Hall form a very handsome pile facing George-street. This hall contains the largest organ in the world. Mr. Boyle was desired to furnish a scheme of ventilation respecting which the City Architect, Mr. Geo. McRae writes: "I shall be very pleased to recommend your ideas regarding the introduction of your system into the Centennial Hall." Mr. Boyle was also requested by the Government architect, Mr. Vernon, to make an examination of the Houses of Parliament, and submit a scheme of ventilation, which has been done. The air-pump ventilators are adopted for the new City Hospital, which, when completed, will cost £150,000, the new Theatre, Conservative Club, Public Library, Exchange, and other public buildings. Indeed, it seems as if the opinion expressed by Mr. J. E. Kemp, architect, is likely to be fully realised when he says: "I am sure that 'Boyle's system' will be universally specified by architects in the colony."

Messrs. Scott, Sibbald and Co., Sydney, have been appointed agents for New South Wales.

DOMESTIC SANITARY APPLIANCES.

MESSRS. ADAMS AND CO.'S new Catalogue (sanitary section) embraces the special appliances required for domestic sanitation, dealing particularly with the trough flushing closet and its modification, the improved latrine, and lavatory basins and fittings, and ordinary house w.c.'s with the waste-preventing cistern, great prominence being given to the flushing and cleaning of the house drains and connections, for which purpose the circular cast-iron flush tank, holding from 15 to 100 gallons, is especially designed. This tank is sunk into the ground and connected to the drain to be flushed. It is provided with a cast-iron lid and sunk dish and grating, upon which the house and other waste, as from a bath, &c., is discharged. Upon the tank becoming full, its immediate discharge through the automatic siphon takes place, and the thorough scouring of the drain results. With this apparatus the whole of the water is utilised for drain-flushing, none being first passed through to start the siphonic action. Where a less costly appliance is required, Adams's patent flushing gully is specially good; this is made in earthenware, the body of the gully holding a certain amount of liquid, from four to eight gallons, as desired.

This flusher does not act with a drop by drop feed, but depends for its start upon a slight increase of head of water, as when a basin, &c., is emptied into the sink, &c., the pipe from which is arranged to discharge over the gully stone. Bath and other wastes are also discharged over this stone, and its adoption enables a householder at a minimum cost to keep his drains in a thoroughly efficient order. The same gully makes, by connecting it to a latrine, a simple and most effective automatic w.c. The self-acting trough w.c. mentioned has been recently greatly improved. The trough in gutter as now made is a most important feature; the whole of the heavier matter sinks into this gutter, and the full force of the discharge from the flush tank is concentrated upon it; less water is thus used, the trough is more frequently scoured, and the cleansing power of the water thus expended is very great. This trough is also fitted where desired with a spray-pipe so arranged as to flush the back at time of discharge of tank.

The patent latrine is flushed out in the same way as the above, but instead of the continuous open trough, it is made of separate and distinct pans placed side by side, and connected together by 6in. pipes. This form gives greater decency and an equally good flushing power. It is more generally used for adult work, barracks, and higher grade schools. It is made in cream-enamelled as well as ordinary brown ware. This firm's lavatory basin for schools is made of strong brown ware, and also in cream and white. It is formed as a solid block of ware with a semi-circular front, and is supported upon a galvanised cast-iron standard. It is one of the best school lavatories made, and when fixed in conjunction with a glazed brick dado is a very marked improvement upon the ordinary run of lavatory basins. Messrs. Adams and Co. have lately patented a very useful appliance for the testing of house drains. It consists of a receptacle into which a special smoke rocket is placed and ignited. It is then closed up, and the flexible tube which is connected to the apparatus being inserted through any closet or other trap, the smoke is thus given off directly into the drain without the trouble or necessity of breaking the ground up for this purpose. The cost is small, and the apparatus of great utility, and should be in the hands of all interested in sanitary work. The same firm have recently patented an improvement upon their well-known flushing siphon for sewers. It was necessary with their earlier siphon that the feed should discharge immediately over the vent-pipe in this siphon. The best features of this siphon have been retained, and by a slight alteration of this vent-pipe it is so constructed that the tank may be supplied with water in any manner and at any point. The

siphon is thus more easy of adaptation than when depending upon a special feed for its supply. Messrs. Adams have recently rebuilt their premises at York, and have laid down additional plant to enable them to keep pace with the growing demand for their specialities, and to turn out their work in the best possible manner.

THE PRINCIPLES OF ORNAMENT.*

PROFESSOR AITCHISON'S edition of Mr. James Ward's treatise on "The Elementary Principles of Ornament" will to some extent supply the want there existed for a text-book on the subject suitable for students of art and of the Science and Art Department. It is concisely written, and convenient in size. Mr. Ward's book was recognised at South Kensington to some extent, but as it was in the lecture form it was too discursive. Mr. Geo. Aitchison, A.R.A., Professor of Architecture at the R.A., the Government examiner in the subject, induced the author to rewrite the work, and has edited it with an introductory chapter of his own. The principles of ornament or the theory upon which the artist proceeds to design are based on various considerations besides geometry. The investigation is one that proceeds from data to principles. There must be the objective and subjective forms of reasoning. Literal transcripts of Nature applied to surfaces or objects are not ornament, as many think it is, though it may be a kind of decoration, and yet not even that, unless it exhibits an endeavour to apply the natural forms.

* Principles of Ornament. By JAMES WARD, Head Master of the Maclesfield School of Art. Edited by GEORGE AITCHISON, A.R.A. London: Chapman and Hall, Ltd.

As the author observes, the units of the decoration must be arranged and brought into order. But ornament must be something more than this; it must carry the principle of arrangement and order into the unit itself—that element must be subjected to the crucible of the mind to discover how far it can be applied, first to the material, and next to the object or form to be ornamented. One of the first things—a very important one—is to discover to what extent is the natural plant or form admissible; in other words, how far should naturalism enter into ornament—how far may the accidental in Nature be carried. These are vital questions upon which all ornamentists are disposed to differ. Certain principles deduced from the growth of natural plants are given in the new Directory of the Science and Art Schools in the form of laws, very excellent and suggestive to students of ornament if they also bear in mind that ornament need not necessarily be imitated. The geometrical disposition of plants and flowers, their manner of growth, and the central type of their arrangements are the main things to study. Roman and Renaissance ornament exhibit these laws if we only endeavour to analyse it. The author deduces the following as the principal ones: "Geometrical arrangement, proportion, stability, repetition, contrast, symmetry, radiation, tangential junction, repose, variety, subordination, balance, unity, series, growth, superposition, fitness." In all good ornament these attributes, or some of them, appear—or, rather, no one of them ought to be contradicted. Some of them are more necessary than others; the necessity of geometrical arrangement is essential; repetition and contrast are also absolute laws of all good design.

Professor Aitchison's introductory chapter is worth reading; he lays stress upon the close study of plants, and the best examples of ornamental art, and says that artists cannot elaborate anything new or beautiful, so long as the public is content "with paraphrases of deceased art, or merely asks for a jumble of discordant scraps." He also values good traditional ornament like the Greek honeysuckle and the acanthus. The last has passed through the correcting and refining hands of Romans, Byzantines, and Renaissance artists, and the late Alfred Stevens has given it a new and, as he says, "peculiarly plastic character" in the Wellington monument. The student will find valuable suggestions on the methods of expression, the different kinds of ornament, such as outlined, flat, coloured, relieved, and shaded elementary forms, the classification of ornament in relation to the space to be filled, of which six kinds are described. The illustrations and diagrams are intended rather to be instructive than as highly finished or comprehensive, and are those the author gave as blackboard diagrams. The glossary will also be found of service to the student.

STEAM OR HOT WATER FOR GREENHOUSE HEATING.

IN order to determine whether steam or hot water were the best for heating greenhouses, a series of experiments have been made at the Agricultural Experiment Station in connection with the Cornell University (New York, U.S.A.), in which the following conclusions were arrived at:—1. The temperatures of steam pipes averaged higher than those of hot-water pipes throughout the entire circuit for the entire period of test. 2. The higher the inside temperature in steam pipes the less is the proportionate warming power of the pipes at a given point. The heat is distributed over a greater length of pipe, and as steam is ordinarily carried at a higher temperature than hot water, it has a distinct advantage for heating long runs. 3. When no pressure is indicated by the steam gauge, the difference between the temperatures of the riser and the return is greater with steam than with hot water. 4. Under pressure the difference is less with steam than with hot water. 5. There is less loss of heat in the steam risers than in the hot-water risers, and this means that more heat in the steam system is carried to the farther end of the house, and more is spent in the returns at bottom heat. 6. This relation is more uniform in the steam risers than in the hot-water risers, giving much more even results with steam than with hot water. 7. When the fires are operative the fluctuation in the temperature of the risers at any given point is much greater with hot water than with steam. 8. An increase in steam pres-

sure raises the temperature in the entire circuit, but the temperature does not rise uniformly with the pressure. 9. The first application of the pressure increases the temperature of the returns much more than that of the risers. 10. Steam is better than hot water for long and crooked circuits. 11. Pressure is of greater utility in increasing the rapidity of circulation of steam and in forcing it through long circuits and over obstacles. 12. Unfavourable conditions can be more readily overcome with steam than with hot water. 13. Hot water consumed more coal than steam, and was at the same time less efficient. This result would probably be modified in a shorter and straighter circuit with greater fall. 14. Under the conditions here present steam is more economical than hot water and more satisfactory in every way, and this result is not modified to any extent by the style of heaters used.

BOOKS RECEIVED.

The Gentleman's Magazine Library: a Classified Collection of the Chief Contents of the Gentleman's Magazine from 1731 to 1868. Edited by GEORGE LAWRENCE GOMME, F.S.A. (London: Elliot Stock).—Part II. of this compilation continues English topography from Cambridgeshire to Cumberland, and comprises notices and original communications of many important places in the counties of Cambridgeshire, Cheshire, Cornwall, and Cumberland. Family history is largely represented in the collection, besides local antiquities, history, local gifts, inscriptions, folklore, &c., which must make these volumes of much value to the county historian, the genealogist, and the antiquary. The architectural notes are of particular interest in describing edifices and ruins which have either been much altered or restored, or now no longer exist. As the editor truly says "The ancient local life of England is departing, and if we cannot altogether regret this, we can still look back upon glimpses of it with some degree of affection and a great deal of interest. It was solid, true, and picturesque." The church cross, the timbered house, the lords' hall are features which are repeatedly brought before us in these 18th century records. The ecclesiastical notes are of particular interest, also the inscriptions on tombs and slabs. Thus the description of Morwenstow Church in Cornwall is instructive as illustrating one of the stages in the history of the Church in Western England. The church occupies a stern headland in the parish of St. Morwenna, named after a daughter of a Celtic king in the 9th century, whose desire was to convert the pagan people. The legend of St. Morwenna is told in full. A font was set up with carved cable coiled round it in memory of the vessel of the fishermen of the East anchored in the Galilean Sea. The writer, the late Rev. R. S. Hawker, ascribes the first foundation of this saint to from A.D. 875 to A.D. 1000. A fine Norman doorway at the south entrance of present church, the font with its cable moulding, the old arches, the symbolic bosses of chancel roof are described. The chancel screen is said to act as the tympanum and to increase and reverberate the volume of sound. But the main interest in this notice of Morwenstow Church is the story attached to the Devil's Door in the north side. It is so named according to the tradition that "it was thrown open at every baptism at the Renunciation for the escape of the fiend, while at every other time it was carefully closed"—an old custom which explains the reason why the northern side of the churchyard is, according to ancient usage, devoid of graves, the north portion of the churchyard being the reputed region of Satan. Other examples of village churches in which traditional usages are found are interesting, and Mr. Gomme's collection of notes is a fund of information that will be appreciated by every student of old English history.—*Induction Coils: a Practical Manual for Amateur Coil-makers.* By G. E. BONNEY. Illustrated. (London: Whittaker and Co., Paternoster-square).—Mr. Bonney has done good service in bringing out a book to meet the wants of amateur electricians who desire a practical knowledge of the accessories and details of induction coils, information on which subject has generally been of a fragmentary nature. The amateur, by the aid of this manual, can make for himself not only ordinary "intensity or spark coils," but medical coils, and the batteries necessary for working them. The book is well printed and illustrated.

—*The Electric Light, Popularly Explained*, by A. BROMLEY HOLMES, M.Inst.C.E. (London: Bemrose and Sons, Limited), is a useful guide to the elementary principles of electric lighting intended for general readers. The technical terms are explained in a simple manner, and the typical examples of dynamos and lamps illustrated. Modes of distribution and the appliances used, and methods of measuring and testing the electric current, motive power, private installations, and cost are among the subjects treated. As a popular treatise on the subject, we can recommend it.—*A Pre-Norman Window at Oxford Cathedral.* By J. PARK HARRISON, M.A. (London: H. Frowde).—In January last (p. 190, last vol.) we noticed a pamphlet by Mr. Park Harrison giving a description of the discoveries of remains of three Early apses at the east end of Oxford Cathedral. The same author now publishes in like form a brochure on further discoveries in the building, including a circular-headed clerestory window in the south transept, and some Early work in the south aisle, which escaped destruction during Sir Gilbert Scott's restorations in 1879. The author suggests that the transept arch and apsidal recess belong to the church of the Holy Trinity, said to have been built by Didanos, the father of Frideswide, circa 735, and that some of the archaic features in the Norman work generally of the cathedral are copied from the remains of this Earlier church.—*The Decorator's Assistant, for Decorative Artists, Painters, Amateurs, &c.*, 5th edition, revised (London: Crosby Lockwood and Son), is a compilation comprising several hundreds of recipes, rules and instructions for mixing, preparing, and using stains, dyes, oil and water-colours, &c., which will be found serviceable for interior and exterior decoration. Painting, as applied to external architecture, is treated by Mr. H. Atkinson, architect; and Mr. Hessel Tiltman, A.R.I.B.A., writes on internal decoration. Many useful rules are given about painting, the combinations of colours, graining and marbling, painting ironwork, the treatment of damp walls, distempers, staining, &c. The recipes are numerous, and are taken from a variety of sources, and contain instructions to clean gold ornaments, picture-frames, hangings, brasswork, oil-paintings, engravings, &c.—*Arithmetic for Schools*, by BARNARD SMITH, M.A., new edition, enlarged by W. H. H. HUDSON, M.A., Professor of Mathematics, King's College, London (London: Macmillan and Co.), is a good handbook for schools and students. The reason of each rule is given, and precedes the rule. The examples are very numerous and complete, with answers, many being taken from examination papers. The work is well printed and arranged. Fractions and square and cubic measure, and decimal fractions are treated, upon rational methods with worked-out examples, rendering these troublesome operations of arithmetic intelligible to the student.—*Transactions of the American Society of Civil Engineers* (June) are to hand. This number contains the address at the Annual Convention, Fortress Monroe, Va., by the president, Mr. Mendes Cohen, and some notes on the Holland Dykes by Mr. William Starling, M.Am.Soc.C.E., and numerous illustrations.

OBITUARY.

WE regret to announce the death of Mr. Edward Ryde, Past President of the Surveyors' Institution, of 29, Great George-street, Westminster. Mr. Ryde, who died at his residence, Poundfield House, Woking village, on Thursday, the 1st inst., from liver disease, was within a few days of completing his 70th year. Mr. Ryde was born at Woking, and on the 20th June, 1837, he entered the office of Mr. James Martin Sanderson, of Sunbury. He served his articles there, and remained with Mr. Sanderson for eight years, being principally engaged during the time upon surveying, mapping, and valuing parishes, under the Tithe and Poor Law Assessment Acts. In 1845 he entered into partnership with Mr. Sanderson, but the partnership was dissolved the following year, and Mr. Ryde came to London. Having laid out and surveyed the direct Portsmouth line from Godalming to Havant, and the Alton and Winchester line, Mr. Ryde was in 1855 appointed surveyor to the South-Eastern Railway Company. About the year 1860 Mr. Ryde opened an office in Parliament-street, Westminster, and five years later he

resigned the detail work of the South-Eastern Railway Company, but remained their consulting surveyor, an appointment which he had ever since held. He suggested and laid out the London Bridge and Charing Cross and London Bridge and Cannon-street lines and stations and bought the land for those railways. He was engaged largely in the purchase of land for, and the sale of land to, railway and other public companies under the exercise of compulsory powers. He purchased the lands for the South-Western extension to Portsmouth, the Ascot and Aldershot, the Netley and Fareham, and the Leatherhead and Guildford lines, and also for the Clapham and Barnes widening of the Windsor line. Land for the Tunbridge Wells and Northampton sewage farms was also purchased by him. Mr. Ryde was concerned in the arbitrations between the telegraph companies and the Post Office on the purchase by the Government of the telegraph lines, and in the arbitrations between the Metropolitan Board of Works and the bridge companies on the freeing of bridges across the Thames. In rating valuations and objections, including most of the great appeals by railway companies, gas companies, water companies, tramway companies, and dock and harbour companies, Mr. Ryde was largely engaged. He was one of the first promoters of the Surveyors' Institution, and ever since its establishment had been a member of the council. He was president of the Institution of Surveyors in 1880-1, and was the first president of the Surveyors' Institution on the granting of the charter in 1881. Mr. Ryde was the author of a scale of surveyors' fees, which is known as "Ryde's Scale." Since March last he had been a member of the Surrey County Council. In 1848 Mr. Ryde married Miss Sarah Harrow, and her death in January last was a great blow to him. He leaves a family of five sons and one daughter. Three of the sons follow the deceased gentleman's profession, and were in partnership with him.

The interment took place on Friday, in the family vault at Holy Trinity Church, Southport, of Mr. John Greenwood, late of Hartwood-road, Southport. Deceased, who was 62 years of age, had long been resident in Southport, where he formerly carried on the business of stonemason and contractor, from which he retired with a competence. Among his more important contracts at Southport for stonework were the Victoria Baths, the Cambridge Hall, All Saints' Church, St. George's Presbyterian Church, and Trinity Wesleyan Hall. Deceased employed above a hundred men, and undertook several important contracts in well-known business premises at Liverpool. From 1884 to 1890 he sat in the Southport Town Council as a Conservative representative for West Ward.

The American papers announce the death of General William Petit Trowbridge, the head of the engineering department of the School of Mines, Columbia College. He was born in Oakland County, Michigan, in 1828. Through the war of the Rebellion General Trowbridge served in the Union Army. In 1870 he was elected Professor of Dynamical Engineering in the Sheffield Scientific School of Yale College, where he continued until 1877, when he was appointed head of the engineering department of the School of Mines of Columbia College. He was a member of several scientific societies, was a voluminous writer, and is said to have been the first engineer to suggest the idea of the cantilever bridge.

A new organ, which has been erected by Messrs. Nicholson and Lord, of Walsall, in St. Mary's Church, Bearwood-road, Smethwick, at a cost of £350, was opened on Friday.

At the last meeting of the police committee for Anglesea Sir Richard Bulkeley offered to give a site at Llangefni for the proposed county buildings. The gift was accepted with thanks, and it was decided to offer a premium of £60 for the best plan for the buildings, the cost to be limited to £6,000. At the same meeting a tender for £2,700 from Mr. William Williams, of Holyhead, was accepted for the erection of a county police-station in that town, under the superintendence of Mr. Richard Davies, architect, of Bangor.

During the restoration of the Abbey Wall, in Marygate, York, recently, the foundation of the bastion, which formed part of the original wall, but had been demolished, was disclosed. This bastion was about 6ft. in diameter, and if restored Mr. Creer, the city surveyor, thinks it would form no obstruction to traffic in the street. Mr. Creer has accordingly received instructions to carry out the restoration.

Our Illustrations.

GOSFORD HOUSE, N.B.

(See description and sketch-plan on page 345.)

CALLE MAYOR, FUENTERRABIA.

FUENTERRABIA (the French Fontarabie) in the province of Guipuzcoa, on the right bank of the Bidasoa, and opposite the French town of Hendaye, occupies a very picturesque position at the foot of the Jaiz-queibet mountains. It is a thoroughly old Spanish town, originally a strong frontier fortress. The walls are now dismantled. In its dilapidation it yet preserves a somewhat haughty appearance, and has been compared to a "ruined hidalgo wrapping himself up in his tattered cloak." The Calle Mayor is a perfect specimen of picturesque originality. Most of the houses were formerly palaces of the old nobility, and though they are now turned into shops, some of the façades are still emblazoned with the bearings of their ancient proprietors, sculptured in high relief. On entering the street by the Puerta Principal, the effect is that of a deep twilight after the broad blaze of the sunny mountains. This is caused by the almost flat roofs, which project considerably beyond the fronts of the houses, and are nearly all supported by carved woodwork, black with age. The massive parish church, dominated by its campanile and lantern, forms perhaps the most important feature of the town. Our illustration is taken from a specially-prepared impression of an exquisite etching by Mr. T. J. Dalgliesh, to whom we are indebted for permission to issue the reproduction printed herewith.

LEWISHAM CENTRAL PUBLIC LIBRARY.

This building is to be erected in the High-street, Lewisham. The whole of the ground floor is to be devoted to the public, saving expense in attendance and supervision. The building will have a frontage of 69ft., and the following accommodation:—Central entrance—to the left, librarian's room, and to the right, staircase to librarian's apartments; large central hall and borrowers' counter, with lending library for 10,000 books; out of this hall, reference library, news and magazine rooms; in basement, store for 10,000 books, with lift to lending library, and spiral staircase; the whole of upper floors are devoted to the librarian, with exception of one large room for board meetings of commissioners. It will be built in red brickwork and Corsham stone dressings, from the designs of Mr. Albert L. Guy, architect, 78, High-street, Lewisham.

CHURCH AT WEST DULWICH.

The design published in this issue is for the extension of a church erected many years ago in

this suburb. The addition consists of two bays of the nave and aisles, an apsidal baptistery forming the western entrance to the nave, from which it is separated by a triple arcaded screen under an inclosing pointed arch. On either side of the baptistery is a porch with outer and inner doors; nearly 300 additional sittings are obtained. The material to be used is Kentish rag externally, with box ground dressings; internally, white brick lining to match the rest of church. The piers are of Box Ground stone, the shafts of blue Pennant, and other internal work of Corsham Down stone. The roof will be tiled; the seats will be of varnished pine. The large west window has a double order, the inner one consisting of detached Pennant shafts carrying pointed arches. The architect is Mr. Edwin T. Hall, F.R.I.B.A., of 57, Moorgate-street, E.C.

"BUILDING NEWS" DESIGNING CLUB: A BRICK SUMMER-HOUSE.

The selected design for this subject was published in the BUILDING NEWS for June 24th last, and a review of the whole of the series sent in competition was issued in our number for June 10th. To-day we print the plan contributed by "Smilash the Goth," and awarded the second place. There remains nothing to add to our former remarks, in which exception was taken to the outline of the roofing; we thought the windows unnecessary, preferring Dutch shutters, and said that the Chinese-like ridge-pole with the dragons on the ends was considered unnecessary. The cornice and treatment over the entry are very prettily managed. The steps should have been solid. The author has realised better than the first-placed designer our intention as to the plaster frieze and ceiling. His cut-brick columns are, however, expensive features, which would not wear well—a consideration of no small importance in the construction of garden-houses, which are often neglected.

GRAND HOTEL, CLACTON-ON-SEA.

MESSRS. ROGER SMITH, SON, AND GALE are the architects of this new hotel at Clacton-on-Sea. We have no further description to hand of the structure.

FITTINGS IN NEW COUNCIL CHAMBER, YORK.

These illustrations, and two more pages we shall give next week, show some of the interior fittings of the above. The work was designed by Mr. Gilbert S. Doughty, architect, of Nottingham, and submitted in competition with twelve other sets of designs last year. The whole is carried out in white oak and wax-polished, with gun-metal fittings. The work has been executed by Messrs. Oldham and Knight, contractors, of Nottingham, in a most satisfactory manner.

The new railway to Baltimore, co. Waterford, will shortly be opened by the Baroness Burdett-Coutts. Mr. Reid is the engineer in charge, and Messrs. Murphy and Co. are the contractors.

In the case of Reuben Cull, of Enfield, Middlesex, and Palmerston-buildings, Old Broad-street, City, brick and tile merchant, trading with R. T. Cull as R. Cull and Son, the discharge from bankruptcy has been suspended for two years, ending July 27, 1894.

A handsome clock and turret have been presented to the town hall, Cardigan, by the mayor, Mr. David Davies. The clock has four large illuminated dials. It strikes the hours and chimes the quarters. It has been made by John Smith and Sons, Midland Clock Works, Derby.

On Monday last a Baptist chapel was opened at Yalding, in Kent; and a short time before memorial stones were laid for new Baptist Sunday schools at Tunbridge Wells. Memorial stones have recently been laid of a Wesleyan chapel, Port Talbot, South Wales; Wesleyan chapel at Eskring, Notts; and of a Wesleyan church parlour and sexton's lodge at Llandudno. The Baptist chapel, Green-lane, Derby, has just been reopened after alterations; and a Wesleyan chapel has just been opened at Whitwell, Notts. The contract is just let for a Wesleyan chapel at Settle, Yorks; for extensive improvements at the Congregational church, London-road, Derby; and for extension of the Wesleyan mission chapel, Mansfield, Notts; also for new Wesleyan schools at Hucknall Huthwaite, Notts; and Annesley Woodhouse, Notts. The Baptist chapel, Abingdon, is to have extensive renovations, the Baptist mission-hall, Bell Green, Catford, S.E., is to be enlarged, and a new Wesleyan chapel is to be built at Eastleigh, Hants. The architect for the whole of the above is Mr. John Wills, F.S.Sc., Derby.

COMPETITIONS.

MERTHYR TYDFIL INTERMEDIATE SCHOOL.—The design submitted by Mr. James Crombie, A.R.I.B.A., London, has been placed first, and he is appointed to carry out the work. The school will accommodate 100 boys and 80 girls, and will have, besides the usual school and classrooms, a gymnasium, workshop, laboratory, art and cooking class-rooms, and a residence for the caretaker.

MANCHESTER TECHNICAL SCHOOL.—The award in this important competition has just been made known, and is as follows:—1st premium of £200, Messrs. Spalding and Cross, 15, Queen-street, E.C.; 2nd, £150, Messrs. Gibson and Russell, 11, Little Queen-street, Westminster; 3rd, £100, Mr. Ernest A. Runtz, 22, Moorgate-street, and Mr. Frederic R. Farrow, 2, New-court, Carey-street, W.C. (jointly); 4th, £75, Mr. Theodore Lington, 53, Oxford-street, Manchester. Mr. Alfred Waterhouse, R.A., was the assessor, and 26 sets of designs were sent in. The technical school is to be built in Whitworth-street, Manchester, and will contain about 144,400 square feet; it will include some thirteen departments, and the cost was limited to £75,000. The instructions stated that Gothic designs were not considered suitable, that the elevations might be of Ruabon brick, and that fireproof construction should be adopted. The competition designs are now on view at the Municipal School of Art, Cavendish-street, Manchester.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

GLASGOW ARCHITECTURAL ASSOCIATION.—The usual monthly meeting was held in the rooms, 114, West Campbell-street, on Tuesday evening, the president in the chair. After the ordinary business was transacted, Mr. Chas. R. McIntosh read a paper descriptive of his tour in Italy, while he was the recipient of the Alexr. Thomson Travelling Studentship. His route took in, amongst others, Naples, Palermo, Rome, Orvieto, Siena, Florence, Pisa, Lucca, Bologna, Ravenna, Venice, Padua, Vicenza, Verona, Milan, and Pavia, the principal buildings in each of which he noted and criticised in a very racy manner. The paper was illustrated by a large collection of admirable pencil and water-colour sketches and some good photographs. A short discussion followed, and a vote of thanks was passed to the essayist.

CHIPS.

Mr. James Brooks, V.P.R.I.B.A., has sustained a great bereavement in the death of his wife, which occurred on the 31st ult. after great suffering from cancer.

A stained-glass window, representing the "Raising of Jairus's Daughter," has been placed in the United Presbyterian Church at Troon, N.B. Mr. William Smith, of London, was the artist.

The rural sanitary authority of Chipping Sodbury, Gloucestershire, has under its consideration reports on the sanitary condition of Yate Workhouse and the outfall drainage at Wickwar, prepared by Mr. J. Fletcher Trew, C.E., of Gloucester.

The county town and borough of Monmouth is about to be entirely resurveyed from plans prepared by Mr. J. Fletcher Trew, C.E., of Gloucester.

The Dean and Chapter have received promises of nearly £5,000 towards the sum of £20,000 appealed for to repair Lichfield Cathedral.

A monument to the distinguished German architect, Gottfried Semper, was unveiled on the Brühl Terrace at Dresden on Friday, in the presence of the members of the Association of German Architects and Engineers, and of the principal authorities of the city. Professor Lepsius delivered a speech recalling the great services rendered by Semper to architecture, while Herr Wiebe, Chief Government Surveyor of Berlin, handed over the monument, which is the work of the sculptor Schilling, to the City of Dresden. Semper was the designer of the new museum and other public edifices at Dresden.

The oldest house in Winchester, the Old Rectory in Cheesehill-street, has just been restored to its original appearance in the reign of Henry VI., and is full of old furniture and occupied by art workmen in wood. Messrs. Kitchen and Thomas are the tenants, and carried out the restoration.

The city council of York are about to seek powers for further extending the boundaries of the city borough in the direction of the townships of Clifton and Huntington, by the inclusion of a suburban area of 263 acres.

WAYSIDE NOTES.

A SATISFACTORY condition of things is reported in connection with the doings of the Commission for the Preservation of Monuments of Arab Art, which, as all interested in Egyptian archaeological matters well know, has its headquarters at Cairo, and seeks to afford a stitch-in-time to the many fine old buildings of that city. Not the least gratifying fact with respect to the Commission is its financial arrangement. Of an annual Government grant of £4,000 E., only £600 E. is devoted to office expenses, which also include the salary of M. Hertz, the able architect to the Commission. The remaining sum is therefore available for restoration purposes, and is devoted to good ends by the members of the Commission, who are said to meet with regularity, and throw much energy into their work.

Since there are some 800 monuments in Cairo registered as worthy of preservation, it may be imagined that the funds of the Commission are quickly exhausted. In the majority of cases the sums paid are small, and devoted simply to patching-up and preserving from actual ruin the various buildings, &c., where decay threatens destruction; but the Commission has expended large sums in several cases. In the repair of the Mosque of Jemâl-ed-dîn, the Ustâd-dâr in Jemâlêya, for example, the sum of £800 was spent; £680 was laid out on the mosque of "Kâdy Jahyâ Zeyn-ed-dîn," and £1,000 for the repair of the old and magnificent mosque of Ifn-Tûlûn. Much more could of course be accomplished if further funds were forthcoming, as the Commission extends its operations beyond the limits of Cairo. All who admire the phase of Arab art that the Commission seeks to preserve, will sympathise with the work of the members of the Commission, and as we hope to some day have an opportunity to visit the architectural wonders of Egypt, the preservation of beautiful buildings from certain ruin should be a matter of direct interest.

I read that the restoration of the "Old Red Hall" at Bourne, Lincolnshire—"Guy Fawkes Mansion"—has now been completed. This is one for the S.P.A.B., who successfully petitioned the Directors of the Great Northern Railway Company with a view of saving and restoring the building when it was threatened with demolition on account of railway extensions.

The necessity for further asylum accommodation everywhere is something fearful to contemplate. Lincolnshire seems to be in as bad a way as any county, and possibly worse, it being stated that lunacy has been on the increase in the county. It is now proposed to erect another asylum. There is, however, it appears, a workhouse at Spalding capable of accommodating 400 persons, and now only occupied by 80 inmates, and an alternative to building another asylum has been suggested—viz., the employment of this building for the reception of lunatics. If it be found that the Spalding Workhouse is always as empty as at the present time, and the building were suitable, it would seem a sensible thing to turn it into an asylum and build a smaller workhouse. The probability is that the building is altogether unsuitable without conversion, in which case all will agree that a new asylum will be more to the purpose and more beneficial to the unfortunate people who would occupy it.

Do painters ever have the subjects and composition of their pictures revealed to them in their dreams? asks the contributor on art matters to the *St. James's Gazette*; and I am caused to wonder in a similar manner whether there ever appeareth in dreams to the architect divers and curious architectural conceptions. That new order or style of architecture for which we have been so long looking may perhaps be some day revealed in this way. Someone there certainly was in history or fiction who used to keep drawing materials, &c., ready to hand in case of any magnificent architectural idea occurring to him in his slumbers. Was it not our old guide, companion, philosopher, and friend—Pecksniff, to wit? The faculty of dreaming architectural compositions would be an invaluable one to competing architects, who, having racked their brains in futile endeavours to find a new outline for the one hundred and seventy-seventh gable in their

design would see the same appear before them with all the glamour and soothing ease of the phenomenon called dreaming. Now I do call to mind that years back I dreamed a dream to the effect that I was to build a tower like one I was shown; but the tower in question was a poor sort of affair, a mere commonplace Renaissance, unworthy of an architect's office-boy—a sort of confectioner's jelly-mould, and positively less architectural than a wedding-cake. It is not a little remarkable that during my architectural career I can call back from dreamland but two instances of any note professionally speaking, and further, it is always something to do with a tower. Not many nights ago a certain Form appeared before me which, according to custom in dreamland, may have been indifferently a tom cat, frying-pan, or sack of coals, but which I have every reason to seriously believe was meant for a sort of sugar-loaf mountain seen at a distance. Anyhow, I was impressed with the solemn effectiveness of the outline, and have had some doubts as to whether, with its battered sides, it did not once and for all show the fallacy of sheer walls when sublimity is desired, notwithstanding all the Alpine precipices and "beetling crags" in existence and the arguments of all the writers on architectural ethics.

Shipbuilding is very slack just at present, if the condition of a "yard" at Middlesbrough is a true indication of the industry in general. It is reported that owing to the difficulty experienced in obtaining new work, Sir Raylton Dixon and Co. have decided to close their No. 2 yard at Middlesbrough as soon as the vessels in course of construction are completed. For some time, it is said, batches of men have been paid off week by week, and it is expected that in a month or six weeks all the hands will be discharged—until quite recently 600 in number.

It is pitiable to think of a body of men having first called to their aid a professional referee, sitting down and deliberating as to whether they are bound to observe his decision. Such appears to have been the case in the competition for the Llanelly Town Hall, where the Local Board, having received Mr. Barry's report, immediately ask whether there is anything binding them to respect the same. It is no great mystery to me how this happens, sad as it is from the point of view of architectural competitors. Doubtless the ideas of a town council do not ordinarily run on pure architectural devices, but would be in the way of something a little lighter and more "ornamental." One can therefore easily understand that there might be a design or two very captivating to even the Cambrian imagination, and there would be a temptation to over-ride the assessors' award, and to adopt the more taking design. This is one of the inevitable evils accompanying the appointment of assessors. If anyone can show how it is to be remedied, a great benefit will be conferred on the profession.

GOTH.

CHIPS.

New and enlarged Wesleyan school buildings at Winchester were opened on Tuesday week. The cost of the alterations has been £1,005, and accommodation is now provided for 400 children. Messrs. Colson and Son, of Winchester, are the architects and Mr. Hutchings is the contractor.

On Saturday the Primitive Methodists at Trimdon Grange, co. Durham, opened a new church. The building is of red brick with stone facings, and of Gothic style. The plans are from the designs of Mr. J. F. Longstaff, Trimdon Grange, under whose superintendence the building has been erected. The builder is Mr. Burn, of Hartlepool. The cost is about £600.

Works of water supply have just been completed at Netherlee-bridge for the Widnes local board. Messrs. C. O. Ellison and Son, of Liverpool, are the architects and Messrs. Henshaw and Sons the contractors.

The Glasgow and South-Western Railway Company are making arrangements for an extension of their carriage and waggon repairing shops at Kilmarnock, at an estimated cost of £4,000, to meet the requirements of their largely increased rolling stock.

A new turret clock, placed in the tower of St. Peter's Church, Peterchurch, was started last week. It has been constructed by Messrs. John Smith and Sons, of Derby, at a cost of £150, and has two six-foot dials.

SANITARY CONGRESS AT PORTSMOUTH.

THE thirteenth annual Congress of the Sanitary Institute will be held at Portsmouth from the 12th to the 17th inst. The proceedings will be opened on Monday next, the 12th inst., by a reception by the Mayor, to be followed by the inaugural address by the President of the Congress, Sir Charles Cameron. On Tuesday, the 13th, five conferences will be held at the Town-hall: one of municipal and county engineers, under the presidency of Mr. H. Percy Boulnois, of Liverpool (and formerly of Portsmouth); another of naval and military hygienists, a third of medical officers of health, another of sanitary inspectors, and a fifth of ladies on domestic hygiene. On Wednesday, the 14th inst., Section I., "Sanitary Science and Preventive Medicine," will be opened by an address by Professor J. Lane Notter, M.D., to be followed by papers and discussions. Section II., "Engineering and Architecture," will commence its sittings on Thursday, the 15th, when Mr. James Lemon, the Mayor of Southampton, will deliver an inaugural address, and papers and discussions will be read on that and the following day. On the Friday Section III., "Chemistry, Meteorology, and Geology," will hold its meetings; and in the evening Dr. W. H. Corfield will give an address to the working classes in the Town-hall. Saturday will as usual be devoted to excursions in the neighbourhood.

THE LARGEST COLD MEAT STORE IN THE WORLD.

THE Civil and Mechanical Engineers' Society visited on Tuesday the new Cold Meat Store of Messrs. Nelson Brothers (Limited), Lambeth. This store is said to be the largest in the world, being capable of holding 270,000 sheep. It was designed by Sir Frederick Bramwell, Bart., and Mr. H. Graham Harris. The store may roughly be described as a brick box 150ft. long by 150ft. wide, and 40ft. deep, buried in the ground to the extent of 20ft. The only openings into it are at the top. Inside this brick box is a wooden one disconnected from the brick wall, and having six wooden floors in it, these being so constructed that cold air can circulate through them.

In order that the unloading of the barges which receive the meat from the ships in the docks below bridge may be expedited as much as possible, a 100ft. jetty has been constructed, which, with a private dock inside the wharf, will enable eleven barges to be unloaded at one time. Ample provision has been made for the distribution of the meat for the purpose of consumption; as many as twenty vans can be loaded at one time.

The cooling is effected by two De la Vergne engines and apparatus, and by two of Messrs. Haslam's cold-air machines. The store is lighted by electricity, and has all modern lifting and other necessary appliances. During the last twelve months two and a half million sheep have been imported by Messrs. Nelson Brothers.

A new pig market is being provided by the Corporation of Birmingham in Montagu-street, to take the place of that in the Smithfield. The market covers in an area of 3,200 square yards. The roof is partly glazed and partly slate, and is carried on iron girders and columns, the walls being of brick, the floors of blue brick set in cement, and the pens of iron. The cost will be about £19,000, and Mr. C. A. Horton, of Brierley-hill, is the contractor.

At a meeting of the building committee and trustees of the United Methodist Free Churches, held at the U.M.F.C. rooms, Markhouse-road, Walthamstow, on Saturday evening last, it was unanimously decided to accept the plans and designs prepared by Mr. J. Williams Danford, M.S.A., architect and surveyor, of 100c, Queen Victoria-street, E.C., for the new church buildings proposed to be erected in Walthamstow. The total cost of the scheme will be about £4,000. Mr. Danford has been instructed to proceed with the work at once.

Part of the Long Mead Estate (about ten acres), at Bishopstoke, has been secured by the County of Hants Land and Building Society. The site is separated from the village and the Fair Oak-road by a stream, and access to the site is to be obtained by a bridge. Mr. Crook, of Swathling, has the building of the bridge for the company, and commenced operations last week. The proposed bridge will be 40ft. wide, and is situate below St. Agnes, on the Fair Oak-road. For the construction of roads and fences, the tender of Mr. J. Butt, of Southampton, has been accepted at £1,006.

Fig 10. Parallel Rays
Inclined planes.

SHADOWS IN PERSPECTIVE.—V.

By ARTHUR VYE PARMINTER.

OUR next study will be that of shadows thrown or received by inclined planes, such as that of a chimney or dormer against the sloping side of a roof. The system is the same in principle as for the foregoing examples, but is naturally a little more intricate, especially for those who have little or no knowledge of descriptive geometry. But attention to the rules and care in drawing the constructional lines will soon overcome any little difficulty that may at first occur.

The rays of light are still supposed to come parallel to the picture plane, and at any given angle to the horizontal plane, as RLI and RL .

We will first take the Fig. 11, and construct the shadow supposed to be thrown by the vertical line Aa against the plane of the roof. We will consider two methods for finding the shadow; each one may be employed when the other is found inconvenient.

We know that, to have the line of shadow of Aa , we must find the line where the plane, passing by Aa and containing the rays of light, intersects the plane of the sloping roof. This line of intersection will be the shadow-line of Aa . A student of descriptive geometry will have no difficulty in finding the line of intersection; but we will proceed in a manner perfectly clear to those who have no knowledge of this science.

Through point A we draw a line Ax to the vanishing point to the left, and from the lower point a , where the vertical Aa meets the roof, we draw a line ax parallel to the slope of the roof plane, and meeting Ax at x . (This line ax is, in reality, not perfectly parallel to the slant of the roof, for all these lines should converge to the aerial vanishing point of the roof; but in ordinary perspective the difference is so slight, that we will not take it into account.) We have now a plane Axa perpendicular to the roof plane, and intersecting it by the line ax . This plane Axa is evidently perpendicular to the roof plane, for the line Aa is vertical, the angle xAa is a right angle in perspective, and the line Ax goes to the vanishing point other than that

of the lines of the roof. We have, therefore, found the line of intersection ax of the roof plane with another plane Axa perpendicular to it. Now the plane and the intersection with the roof that we wish to find is a plane parallel to the picture plane, and containing the rays of light. We must, therefore, turn the plane Axa on the vertical axis Aa until it becomes parallel to the picture plane. To do this we draw from A a horizontal line $Ax1$, and from x a line from

the vanishing point to the right, meeting the horizontal $Ax1$ at $x1$. We join $x1a$. The plane Axa is now brought parallel to the picture plane in the plane $Ax1a$, the point x becomes $x1$, and the line Ax is now the horizontal $Ax1$. The line of intersection with the roof ax is now $ax1$, and is the intersection of the plane $Ax1a$ with the roof. A line from A in the direction RLI will give us the shadow point of A at $a2$; therefore, $aa2$ is the shadow line of Aa .

The second method may seem simpler. From a we draw ax , representing the slant of the roof,

and meeting any of the horizontal lines (in perspective) of the roof; say, the eaves at x . From x we draw a line $xa3$ to the vanishing point, and find the projection of a thereon at $a3$. The point $a3$ is now on a line perpendicular to the line of the eaves, and is contained in the plane $aa3x$, in the same plane as Axa . We bring this plane $aa3x$ parallel to the picture planes by means of the horizontal line $aa3a1$ meeting the line of the eaves at $a1$. The plane $aa3a1$ is parallel to the plane of the picture, and is in the same plane as $Ax1a$. A line from $a1$, through a , to $a2$ gives us $aa2$, the shadow line of Aa . Thus by means of either method we arrive at the same result.

Let us now turn to Fig. 10, and construct the shadows thrown by the chimneys and dormer window. For the chimney ABD , we will employ the first system; the student may test its correctness by means of the second method. We have to find the shadow lines of the vertical angles of the chimney $Aa1$, $Bb1$, $Ob1$. We prolong the line $a1$, $b1$, representing the slope of the roof, and from B we draw a line to the vanishing point, and meeting $b1a1$ prolonged at 01 . From 01 we draw a line from the other vanishing point, and meeting the horizontal line drawn from B at b , join $b01$, and from B draw the line in the direction of the rays of light RLI , meeting $b01$, at $b2$; $b1b2$ is the shadow of $Bb1$. Likewise from point A we draw the horizontal line Aa , meeting the line from the vanishing point at a . The intersection of the line joining $aa1$, and the light line from A at $a2$, gives us the shadow point of A . Point $c2$, the shadow of c , will be the intersection of the line from $a2$ to the vanishing point, and the line of light from c .

For the shadow of the chimney on the crest of the roof, we will suppose that the point of meeting of the line 00 and the line from x , representing the angle of the roof, is inconveniently placed. We may take any other point—say, the point X on the line xX , and from this point X draw the lines from the vanishing points and the horizontal line from $x1$, meeting them at $x1$, $x2$. The shadow point of 0 will be 02 , and the shadow line of $0x$ will be $02x$.

To construct the shadow of the dormer window we will employ the second method (it would be good practice to verify the result by means of the first method). From x , the lower point of Ez , we have the line xx , representing the angle of the roof. From x on the eaves we draw the line xe to the left vanishing point, and find thereon the projection of Ez at e . A horizontal line from e meets the eaves at $e1$, the line from $e1$ through x , and meeting the line of light from E at $e2$, will give us $e2x$, the shadow line of Ez . Similarly for the shadow of point G , we find its projection on the roof plane at z , and draw zx , the slant of the roof, and by means of the line from x on the eaves to the vanishing point, we find the projection g of G on the horizontal plane. The horizontal from g will give us $g1$, and the line from this point through x gives us the point $g2$ on the line of light from G . The shadow of point f is found in a similar manner by means of its projection on the roof at f . We have thus $f2g2$, the shadow line of FG ; $f2H$ joined is evidently the shadow line of FH . Or the shadow of F may be more conveniently found by means of the first method, and the lines to the vanishing points from H . The student will easily find for himself the shadow of the slanting eaves against the gable by means of the constructional lines ab , bc , &c.

The construction of the shadows of the eaves of the house against the wall plane should present no difficulty, for it is simply a repetition of the last article for vertical lines, the points VV , &c., being contained by these vertical lines. V is a point on the vertical line Vv at a certain distance from the wall-plane Wv . We draw from any point on the vertical line Wv —say, the point w —lines from the vanishing points, and from the lower point V obtain a horizontal line, meeting the line from w at $V2$. The intersection of the vertical from $V2$, and the line of light from V gives us $V1$, the shadow point of V . The line $V1$, $V1$ from the vanishing point is therefore the shadow of VV . The shadow of the eaves at S and AA is found in a similar manner. The shadow of AA is, however, stopped by the projecting window board; we therefore first find the shadow as if thrown against the wall, and then the intersection of the plane of the shadow with the projecting board, giving us aa , the shadow of AA on the board. The student will construct for himself the shadow cast by the window-board. The shadows of the slightly projecting rafters are found by means of lines in the direction of the rays of light meeting the shadow lines already obtained of the eaves.

A new organ, built at a cost of £500 by Messrs. Harrison and Harrison, of Durham, was opened in the Baptist chapel, Idle, near Bradford, on Friday.

A large block of residential flats is in course of erection near the Minet Library, Knatchbull-road, Brixton. The floors are constructed of steel girders set in cement. Each set of three rooms, with a scullery and offices, is self-contained within a door opening from the central staircase. The Co-operative Builders are the contractors, and the property belongs to the Tenant-Co-operators' Company, Limited.

The Lord Mayor of London inaugurated on Monday the completion of the sea-front improvements at Rhyll, which have been accomplished by the Rhyll Commissioners during the past twelve months at a cost of nearly £10,000. The principal works have been the asphaltting of the promenade, the erection of several shelters and ladies' cloak-rooms, and the provision of a fountain in the centre of the esplanade.

At a meeting of the board of management of the Midland Deaf and Dumb Institution, held on Monday, September 5th, the Mayor of Derby in the chair, Mr. W. J. Phillips was appointed clerk of the works for the new institution now in course of erection in Friargate, Derby, at a cost of over £11,000. Mr. Phillips has had very considerable experience as a clerk of works, and is now engaged at a large mansion which is being erected in Maidstone under the superintendence of Messrs. A. Waterhouse, R.A., and Son.

The Aylesbury extension of the Metropolitan Railway, opened on the 1st inst., from Chalfont-road to Aylesbury, is 16½ miles in length, and has been built at a cost of £380,000, or £22,000 per mile for land and works, the price paid for land averaging £238 per acre. Mr. J. T. Firbank was the contractor. It reduces the distance between London and Aylesbury, hitherto 43 miles by the North-Western route and 50 miles by the Great Western, to 39 miles.

Building Intelligence.

BLACKPOOL.—Messrs. Maxwell and Tuke, the architects, report satisfactory progress of the works of the tower. Messrs. Neill have now completed their contract for the foundations of the tower and for the foundations of the brick keep surrounding the tower; and the contract for the superstructure has been let to Messrs. James Cardwell Brothers, of Blackpool, who will proceed at once with the work. Messrs. Heenan and Froude are proceeding rapidly with the preparation of the ironwork in the yard, and the actual erection of the tower pillars has been commenced. The first group of pillars, 55ft. in height, has indeed been completed, and the steelwork for the second group is on the ground.

NEWCASTLE-ON-TYNE.—The Station Hotel adjoining the Central Station has just been completed for the North Eastern Railway Company. It has a frontage of 310ft. 6in., and is five stories in height above the ground floor. It is Italian Renaissance of a severe type in style, and has been designed and carried out by Mr. William Bell, the N.E.R. Co.'s architect, the chief clerk of works being Mr. Richard Story. Burmantoffs faience from Leeds is largely utilised for decoration. The contractor for the whole building was Mr. Walter Scott, under whom the following sub-contractors have carried out the different classes of work:—The Leeds Fireclay Co., faience work; R. Hardman, Powell, and Co., Birmingham, balustrading; Benham and Sons, London, cooking and hot water, &c.; Messrs. Diespecker and Co., London, Roman mosaic work; Mr. J. F. Ebner, London, the parquet flooring; Messrs. Emley and Son, Newcastle, marble work.

CHIPS.

At Tuesday's meeting of the city council of Worcester it was decided to invite Messrs. T. and C. Hawkesley to submit plans and estimates for a sewerage scheme for the city.

Memorial stones of a Congregational manse were laid at Snodland, Kent, on Friday. Mr. Tomlin, of Snodland, is the contractor.

The foundation-stone of a new Congregational church at Ashton-on-Mersey was laid on Saturday last. The building will have seating accommodation for 350 persons, and will cost £2,000. The contract is being carried out by Mr. J. E. Dean from the designs of Mr. Thomas W. Cubbon, architect, of Birkenhead.

The foundation-stone of the free public library for Southampton was laid by Mr. James Lemon, F.R.I.B.A., the Mayor, on Wednesday week. Mr. E. J. Guy, of Portsmouth, is the architect, and Messrs. G. Scammell and P. H. Dowdell, of Portsmouth, are the contractors. The cost will be £3,500.

Contractors' men are now making preparations for sinking a trial cylinder in the Forth about 660 yards below the entrance to the river Carron, to ascertain the nature of the strata, with a view to preparing plans for a proposed new deep-water entrance and new docks for Grangemouth. The cylinder is to be sunk out in the channel at the depth of 15ft. at low water, and the work has been entrusted by the Caledonian Railway Company to Messrs. Lucas and Aird, Westminster, who are at present constructing the West Highland Railway.

The removal of the flagstaff upon the summit of the Round Tower turret at Windsor Castle, owing to its unsafe condition, was commenced early on Saturday morning. The flagstaff was erected about 1829. The height of the mast, which was of Norwegian pine, was upwards of 70ft., of which 52ft. was visible above the parapet. The new mast is to be supplied by the Admiralty, and will be erected upon the tower before the return of the Queen from Scotland.

The Roman Catholic Bishops of Scotland have decided to erect a new college at Blairs, to take the place of the present institution, St. Mary's College. The new college is to provide accommodation for 100 students, in addition to laboratories and classrooms, and quarters for the rector and professors. The cost will be about £20,000.

The Manchester city council resolved, on Wednesday, after a long discussion, that the recent report presented to them on the Ship Canal affairs, together with a letter from Lord Egerton of Tatton soliciting a further loan of at least one million and a half from the corporation to the Canal Company to complete the works, should be referred to the Ship Canal special committee of the corporation to investigate, and to report the terms and conditions on which they would recommend that the assistance should be rendered.

Engineering Notes.

ABERDEEN.—Extensive additions to the gas-works, estimated to cost £80,000, were sanctioned on Monday by the town council of Aberdeen. In order that the works may be carried out applications will be made to Parliament in the ensuing session for a Bill to authorise the Council to borrow an additional sum of £90,000 in connection with the gas undertaking. The Council had before it reports on the proposed works by Mr. Samuel Stewart, Greenock, and Mr. Alexander Smith, the Aberdeen gas manager. According to these, the bench containing 80 retorts, heated by the open furnaces, will be reconstructed, so as to contain 128 retorts on the regenerative system. This alteration will give retort power for about four years. The present gasholder capacity is 2,100,000cu.ft., while the largest daily consumption last winter was 2,300,000cu.ft., and to remedy this there will be erected an additional gasholder of at least 3,000,000cu.ft. capacity. Another retort-house, to contain 224 retorts, will be built alongside the present one; and an additional purifier-house, scrubbers, and condensers will be built as required.

THE INVERNESS AND AVIEMORE LINE.—The directors of the Highland Railway Company have resolved to proceed at once with the construction of the last section of the new direct line from Inverness to Aviemore and the south, the deviation and shortening of which recently received Parliamentary sanction. The new line is to commence at Inverness, and running up through Culloden wood, will be carried over the river Nairn by a stone viaduct of 570 yards in length, and from 58ft. to 129ft. in height. There will be 27 arches of 50ft. span, while the central arch will have a span of 100ft. The deviation line, which is over seven miles in length, will terminate at Culdoich, from which point to Carr Bridge large squads of workmen are at present engaged in the work of construction. From Inverness to the Nairn viaduct there will be a double line of rails; but beyond that point the line will be single. A station is to be erected near Culloden Moor. The first section of the line, from Aviemore to Carr Bridge, has already been opened.

SUNDERLAND.—The Marquis and Marchioness of Londonderry visited Sunderland on Friday for the purpose of placing a block in the Roker Pier, which is at present in course of construction for the river Wear commissioners. The length of the pier will be 2,900ft. It is six years since the foundation-stone was laid. The foundations are composed of huge bags of concrete, varying in weight from 56 tons to 116 tons. The superstructure is composed of huge blocks, some as heavy as 45 tons. Last year the commissioners decided to proceed with a pier 2,870ft. long, to protect the harbour from the south-east, which is now progressing satisfactorily. These two piers, when completed, will inclose a harbour having an area of 125 acres, with an entrance 600ft. wide, and a depth of water of 45ft. The total outlay on the scheme will be £400,000. Mr. H. H. Wake is the engineer.

The sub-committee of the town council of Edinburgh charged with the carrying through of the arbitration with the North British Railway Company regarding the price to be paid by the company to the corporation for the portion of the East and West Princes'-street Gardens, which have been appropriated for railway purposes, have resolved to claim £150,000 compensation. There are about two acres scheduled. The arbitration will come on for hearing in the first week of October. The Right Hon. Baron Shand is the umpire.

A bacon factory is in course of erection at Ashford, Kent. It is being carried out by Mr. Henry Knock, builder, of Ashford, and satisfactory progress has been made. The chimney shaft has already been commenced, and has been raised to a height of 10ft. The factory, which is under the supervision of Mr. Henry J. Jeffery, M.S.A., architect and surveyor, of Ashford, Kent, will stand upon a spacious site near the Victoria Mills, and a siding by the South Eastern Railway Company has been made.

The town council of Aberdeen resolved on Monday to proceed with the lighting of the eastern district of the city by electricity, at an estimated cost of £24,000, in accordance with the report of Prof. Kennedy, of London. About 7,000 lamps of eight-candle power will be provided.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 832, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and SIXPENCE for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL, XLII, XLVI, XLIX, L, LI, LIV, LVIII, LIX, LX, LXI, and LXII may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—F. G. and Co.—S. African.—B. S. M.—Thos. Geo. N.—G. R. and Y. B. Co.—P. D. (Dublin).

Correspondence.

SUITABILITY OF SITES FOR THEATRES.

To the Editor of the BUILDING NEWS.

SIR,—My attention has just been drawn to your report upon the evidence given before the Select Committee on Theatres, and in criticising my evidence you assume that I disregard the question of suitability of site.

In this you are wrong. The evidence I gave was that a theatre should be erected on a suitable site; but the first consideration, having obtained a site upon which a sufficient number of exits could be obtained, was that there should be every endeavour to make a building as far as possible fireproof, and I put this before the absolute isolation of a theatre site.

It was only upon this question of the absolute isolation that I considered there could be any disregard of the question of site, and in my evidence I clearly pointed out that there should be at least two sides open for exit purposes.

I trust that you will give me space to draw attention to these facts, as certainly your criticism does not fairly represent the evidence I gave, or my opinion as to the necessity for suitable sites of a theatre.—I am, &c.,

WALTER EMDEN.

105 and 106, Strand, London, W.C., Sept. 5.

THE GUILDHALL.

SIR,—I have read with interest your article in the BUILDING NEWS of last Saturday. There is one paragraph in it I should like to correct, as it might mislead. You say that the present roof over the Guildhall was designed by Horace Jones, "with the assistance of Digby Wyatt, F.S.A., and Edward Roberts, F.S.A."

This is scarcely correct. The roof was designed by Horace Jones, without any assistance; but Sir Digby Wyatt and Mr. Roberts were called in early in 1864 by the committee to advise as to whether or not the roof which had been designed by Mr. Bunning, the previous City architect, then recently deceased, and was already contracted for at the time of his death, was an "open roof" as intended by the committee, and was in accordance with the period of architecture of the hall.

The two gentlemen referred to went into the matter, and made a report to the effect that the roof did not answer these conditions, and upon that Mr. Horace Jones prepared the design for the present roof, Sir Digby Wyatt and Mr. Roberts having nothing whatever to do with it.

I enclose you a printed copy of the reports in the matter, which will show you exactly how the matter stood. These reports are accompanied by printed sketches showing what was believed to be the original roof (according to "Smith's Print") which was destroyed in the great fire of 1866; the flat-ceiling roof which existed down to 1864, the outline of the roof designed by Mr. Bunning, and which I have filled in more in detail for your information; and the existing roof as designed by Horace Jones.

I remember at the time a very interesting discussion took place on the subject of what form did the original roof take, a very great number taking the view in opposition to Sir Horace Jones, Sir Digby Wyatt, and Mr. Roberts, that Smith's print did not correctly represent the original roof, there being no evidence amongst the old remains to point to such a roof.

Mr. Charles Bailey, who was at that time chief assistant in this office, and well known as an archaeologist, always maintained, and I think with some show of reason, that the original roof of the Guildhall was carried by arches spanning the entire width, these arches supporting the purlins; and this discussion was revived at a meeting of the R.I.B.A. in either 1864 or 1865, when the late Sir Horace Jones read a paper upon the Guildhall.

It is perhaps of no great importance; but it is just as well that little matters of this kind should be known correctly.—I am, &c.,

A. MURRAY,

Guildhall, E.C., Sept. 7. City Surveyor.

BERGEN CHURCHES.

SIR,—Your versatile correspondent "Goth," in the current week's issue, refers to a new Norwegian church at Bergen, built entirely of paper. I happened, on my return homeward-bound a few weeks ago from a cruise in the Arctic regions, to spend a bright and happy day at Bergen, and noticed a large brick church with a western tower in course of erection there, but contrived to miss the paper church in question.

But even in Norway things are not always all they seem! For instance, I formed one of a very pleasant party at Bergen who drove out to Fjøsanger, a few miles distant, to see an ancient wooden church, which originally stood at Fortun, but some few years ago had the mis- "fortune" to be purchased by the resident American consul, Mr. Gade! He removed it to his own picturesque grounds, where it has been re-erected, and by its side, upon a mound, an interesting old granite cross—also evidently an acquisition!—has been placed. This cross is fashioned out of a roughly-hewn and very thin slab—the thinnest I ever saw in that material. It has an incised cross upon it, on one face.

As for the old church, judging from external appearances (we were not fortunate in getting inside), very little appeared to be original. It is built entirely of pine. Only the two doors and some panelling seemed to be any thing like Mediæval work. Both the former were got out of single planks—remarkably fine ones, and about 3ft. in width, with some rather nice ironwork upon them. The rest of the exterior of this quaint edifice did not seem to be anything like so old as myself; much was quite new, and daubed over with a sticky, treacle-like varnish.

My visit was of necessity of so superficial a character that I had really little opportunity for examining the church closely, and none, as already said, for seeing the inside at all.

Some particulars relative to this building would probably be read with interest by many, as well as by,—Yours, &c.,

Exeter, Sept. 3.

HARRY HEMS.

Intercommunication.

QUESTIONS.

[10842].—Composition for Renovating Stone-work.—Would one of your correspondents kindly inform me of some reliable composition for making good a stone garden-wall that has been affected by the frost?—J. C.

[10843].—Colour Washes on Parchment.—Will someone kindly inform me how to tint conveyance plans on parchment evenly and without cockling? Is there any special treatment, medium, or process required?—KORAX.

[10844].—Lightning Conductors, &c.—Can any one kindly give me sizes of lightning conductors usually used? Does difference of size depend on locality, whether on hill or in valley, or on size of building? Is there a graphic way of finding strains in the side-plates and lattice bars of a support for a weight of, say, two or three tons, or is there any formulæ? Support is of wood.—WILLIAM BOND.

[10845].—Paints.—Will some kind reader tell me how silicate paint is made—if ordinary white lead could be made into same by a mixture of silicate of soda? If so, how? Being situated in the opposite side of the world to where your favoured readers are, I cannot get the above information.—RANGON.

[10846].—Hydraulics.—Can the pressure on the piston of a hydraulic press be ascertained from the following particulars when the stroke of the ram or pump is not given; and if so, by what formula: Piston, 6in. diam.; pump-barrel and pipe leading to piston cylinder, 3in. diam.; pump, ram or piston, nearly 3in. diam.; lever operating ram, 4ft. 2in. long; ram, 2in. distant from the fulcrum; and force of 2cwt. to be applied at end of lever arm. From this the pressure obtainable seems to be 49cwt. per area of ram, or about 95cwt. per square inch at the pump.—PERPLEXED.

[10847].—Lime and Paint Stains on Slate Mantel.—Could any reader inform me of the best way of removing lime and paint stains from a polished black slate mantel and jamb, also on kitchen range? I can manage to get a few of the mortar patches off, but it leaves a mark in every case.—RANGE.

REPLIES.

[10833].—Timber and its Position.—It was stated in a recent American journal on carpentry that staves placed inversely to their natural direction in the tree lasted longer than where put in their natural position, though I am inclined to doubt the assertion. Perhaps some experienced reader on the subject will throw light and give reasons for such an assertion.—PHILO.

[10834].—Stresses in Cranes.—Draw lines to represent forces caused by the load on the jib-head; the resultant diagonal of parallelogram will represent the stress on jib. This stress is opposed by the jib and tie-rod. Draw a line parallel to the jib from the end of above diagonal, and another at its end parallel to the tie-rod, forming a triangle. Measuring the line parallel to jib, we find the compressive force coming upon the jib.—E. H. G.

[10835].—Electric Lighting.—Switches for turning the lamps on and off are conveniently fixed at the entrance to the room. In a bedroom it ought to be at the side or head of the bed.—ELECTROLIER.

CHIPS.

The syllabus of the classes of architecture, building construction, and modern practice at King's College, London, conducted by Professor Banister Fletcher, F.R.I.B.A., has just been published. The courses extend over three years, and are specially arranged for preparation for the progressive examinations of the Institute of Architects. The Michaelmas term opens on October 10th.

The city council of Gloucester have received a report from Mr. Fox, C.E., on the alternative schemes of water supply for the city. After seeing the confirmatory opinion of Mr. James Mansergh, C.E., he reiterates his previously-expressed recommendation, that the best course will be to bore in the newest red sandstone strata, failing which there is nothing, he thinks, for the city but to take its supply from the river Severn.

A memorial of the son of the incumbent has just been placed in the Church of St. Saviour, in Aberdeen-park, Highbury. It takes the form of a statue of our Lord as the Good Shepherd, executed a little under life-size in white alabaster, and standing under a carved canopy, on a corbel of stone. It has been executed by Mr. Harry Hems, of Exeter.

The Airdrie Dean of Guild Court has passed the plans for the erection of a suite of offices and board-room for the new Monkland Parochial Board on a site contiguous to the Free High Church in North Bridge-street. The premises are to consist of the inspector's offices and offices for the collector of rates, as also a board-room and other apartments in the upper story. The plans have been prepared by Mr. George Arthur, architect, Airdrie, and the estimated cost is about £1,200.

Building operations have been commenced for the erection of forty villa residences situated on the Rotton Park Estate, Birmingham. The total cost is estimated at about £15,000. The contractor is Mr. Edward Airey, of Gillott-road, and the architect Mr. J. Statham Davis, of 53, Newhall-street, both of Birmingham.

Legal.

A BUILDING CONTRACT.

THE courts of law have certainly gone as far as possible in enforcing the claims of a building contract against the builder, by whom it is often too lightly signed. But to charge a builder with stealing his own plant and materials because they were contracted to become the property of the prosecuting freeholders in certain events, is more than the law can stand. This, however, was attempted in the recent case of "The Queen v. Walters" (*Times*, August 7th), and a conviction was actually obtained at the West Kent Quarter Sessions, which has since been quashed by the Queen's Bench Division. It was an ordinary building agreement in the usual form, entered into between the freeholders of the land and the builder, under which the latter agreed to build certain houses. There was the customary proviso that the freeholders could take possession of the land on any default, and of the houses, and of all plant and materials thereon. It was admitted that they had not so taken possession when the builder removed his plant and materials, which he was now charged with stealing. It was contended on behalf of the prisoner that the agreement did not vest the plant and materials in the freeholders until they took possession under the forfeiture clause, and so there could be no larceny by the builder, as the things were his own property until that occurred.

The Queen's Bench Division made very short work of the conviction, and Lord Coleridge remarked that had not the case been actually reserved by a Quarter Sessions, it might have been thought impossible that such a construction could be put upon the agreement. They held that the forfeiture clause was in the nature of a penal measure to compel the builder to perform his contract. Under it the freeholders had power to re-enter and take possession of the land, and also the buildings, together with all materials, and even the plant and tools belonging to the contractors. When they did so take possession these things would become their property, and a charge of larceny for removing them after this could have been maintained. But the present conviction was based upon a construction of the clause by which the moment the plant and materials were brought upon the ground by the builder they would pass into the possession and become the property of the freeholders, who could therefore have at once seized and sold them, even though there had been no default. This construction proved too much. The Court accordingly quashed the conviction, as the builder could not steal his own plant and materials.

FRED WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

PROVINCIAL.—BUILDING PLOTS.—This is not a question of law, but of professional practice, I should say, and one in which you might well consult an experienced architect and surveyor who has had to deal with similar difficulties.

C. O. S. AND S.—BUILDING CONTRACT.—The further facts now supplied modify this matter. But, according to these terms, I think the Board has a right to have a copy supplied to them, sealed up as agreed, and only to be used by them for comparison with final account. I do not see how that request, if so made, can be refused.

At a special meeting of the Stratford-on-Avon rural sanitary authority, held on Friday last, communications were received from the Local Government Board as to the alleged insanitary condition of Henley-in-Arden. It was decided to instruct Mr. J. E. Willcox, of Colmore-row, Birmingham, to prepare a general drainage and water scheme for the village.

The town council of Bury, Lancashire, who are threatened with legal proceedings under the Rivers Pollution Act of 1876, recently decided to proceed with a sewerage scheme at an estimated cost of £100,000 in order to keep the sewage out of the rivers Roach and Irwell. A poll of ratepayers was demanded, however, and these have proved adverse to the scheme by a majority of 800; but more than 2,500 papers were returned blank, and over 1,800 were not collected. The town council has therefore referred the matter again to a committee to report and offer recommendations.

LEGAL INTELLIGENCE.

ANCIENT LIGHTS.—JOHN G. JOICEY v. NORTH-EASTERN RAILWAY COMPANY.—This arbitration case was held in Newcastle-on-Tyne on the 3rd and 4th ult., the umpire being Mr. Robt. Vigers, of London, the arbitrators being Professor Banister Fletcher and Mr. Thos. Gow. For the claimant there appeared as counsel Mr. Cyril Dodd, Q.C., M.P.; as solicitor Mr. C. E. Cadle (representing Messrs. J. G. Wilson, Ormsby, and Cadle, of Durham); and as expert witnesses Mr. James W. Frazer, A.R.I.B.A., Mr. E. E. Clapham, Mr. John Fergusson, and Mr. W. S. Armstrong, of Newcastle. For the railway company there appeared as counsel Mr. Fletcher Moulton, Q.C., with, as junior counsel, Mr. Hugh Boyd; as solicitor Mr. A. Kaye Butterworth, the company's own solicitor; and as expert witnesses Mr. Chaffield Clarke, F.R.I.B.A., of London, Mr. Henry Carrick, Mr. Joseph Potts, and Mr. Geo. Irving, of Newcastle. This was a case in which the claimant's property containing the ancient lights is situated in Pottery-lane, Newcastle, having a 30ft. street between it and the railway company's Forth Goods Station. The railway company formerly had a wall opposite about 17ft. 9in. high, and in extending their goods station under statutory powers they pulled down this wall and erected their station to a height of about 52ft. The claimant claimed that this addition seriously affected the light to his premises. It was proved that the workmen engaged in the premises (which are occupied by an engineering firm) felt the loss of light to such a large extent that they could not work with comfort without the aid of artificial light, and then they were unable to execute the same quantity of work as was executed before the obstruction was there. The railway company called their witnesses to prove that with an alteration to the front of the building, which is 125ft. long, by setting back the first-floor wall 3ft. and inserting skylights to light the ground floor, all the light that was necessary could thus be obtained, and that the cost of such alterations would only be about £200. It was pointed out by the claimant that that amount was inadequate, as the same amount of floor space would have to be retained, therefore the back wall would have to be set back 3ft., and the roof and floors taken down, and replaced perhaps with new material. This alteration would, it was argued by claimant, cost about £2,500, and then not give the same light as before enjoyed. The claimant claimed £5,460 on the ground that, having prepared a scheme for the improvement of the property, in the form of warehouses, offices, and sample rooms, he was prevented from carrying it out, as the risk would be too great, seeing that the majority of the light which he required for the offices and sample rooms would be taken away, and that was the amount he had lost through having to abandon the scheme. The railway company argued that the scheme would not be interfered with to the extent that plaintiff set forth. The award was taken up by the railway company on the 26th ult., and was found to amount to £1,218.

NON-PARTY WALLS.—Messrs. Black and Son, builders, of Perry-vale, Forest-hill, were summoned to the Greenwich Police-court on Tuesday by Mr. Jolley, district surveyor of Sydenham, for "separating a building known as No. 22, Dartmouth-road, from an adjoining building known as No. 24, Dartmouth-road by a partition other than a party-wall constructed of brick, stone, &c., &c.," and also "for placing woodwork nearer than 4in. to centre line of party-wall between No. 24 and No. 26 adjoining, &c., &c." The premises in question are known as Nos. 22 and 24, Dartmouth-road, and were partially burnt down some five months ago, the inclosing walls still remaining. They consist of a large shop and a small shop, both communicating by a door, and over each shop are rooms accessible from each shop by two staircases, one in each shop. There was no communication between the two portions of the building on the upper floors. Each shop has an entrance from without. With respect to the second part of the summons, the wall in question divides No. 24 from No. 26 for a certain distance vertically, leaving a height of 5ft. of wall above this point, and which is utilised by No. 24 as an external wall, having in fact, a window (ancient lights) in it which overlooks the roof of No. 26, and 18in. above it. The alleged irregularities mentioned in the summons refer to the upper portion of this wall above No. 24. The case had been twice before adjourned, and Mr. Tolley had said that, in his opinion, Sec. 28, rule 1, and Sec. 27, rule 3, were sufficient in themselves to prove that the premises Nos. 22 and 24, were two buildings, and not one building, which was the real point at issue on the first part of the summons, and pointed out to Mr. Kennedy, the magistrate, that the plans showed two shops, and two separate entrances and staircases from without. The defendant's solicitor, Mr. Frank Wm. Brazil, contended that, in spite of what Mr. Tolley had said, the premises were one building within the meaning of the Act, inasmuch as there was an internal means of communication between

all parts thereof, and there would be no very great objection to having two, three, or even six doors in the alleged party-wall between Nos. 22 and 24, if the Act so required it; but submitted that, for the purpose of the Act, one door sufficed. Mr. Brazil also pointed out that the building was an "old building," inasmuch as one half thereof had not been taken down (Sec. 10), and that as the means of communication still existed between Nos. 22 and 24, and always had existed, it was outside the jurisdiction of the district surveyor to have it blocked up; the premises could not be held to be two buildings, and that no wall could be a party-wall with a door in it. Mr. Tolley, however, in answer to this, argued that all buildings were now buildings that were built after January 1st, 1856 (see sections 7 and 8), and that he would therefore be empowered to order the opening to be blocked-up. Mr. P. H. Adams, of the firm of Messrs. Adams and Mann, architects and surveyors, gave evidence to the effect that he had prepared the plans with a view to compliance with the Building Act. On the second point, as to whether a wall can be a party-wall below and an external wall above, Mr. Brazil pointed out that the definition of the word "party-wall" would prove that it could. The upper part was not "used" as a party-wall, nor "built in order to be used," as it had got an ancient light in it. The cases of "Cubitt v. Porter," and "Watson v. Arnold" were cited to strengthen this reading of the Act. Mr. Tolley, on the contrary, pointed out that a case had been tried at Greenwich Police-court some years ago, that was on all fours with this second point, and in which the magistrate shared his own present views of the case. On both points Mr. Kennedy reserved his decision until Tuesday, September 20.

WATER SUPPLY AND SANITARY MATTERS.

GLENGOWAN, N.B.—A special water supply has just been completed for the village of Glengowan, Caldercruix, by Messrs. John Spence and Sons, engineers, Airdrie, the contractors, for the Lanarkshire County Council. The supply is obtained from natural springs near the Edinburgh and Glasgow Road. The water is conveyed in a 2-in. cast-iron pipe, which crosses the lade at Caldercruix mills and the river Calder upon wooden beams, and then is carried to an iron gathering tank holding 16,000 gallons.

CHIPS.

Mr. Harry Simmonds, builder, of St. John-street, Monmouth, attempted to commit suicide by hanging himself to a beam in his workshop on Monday. The rope broke, and Mr. Simmonds fell a distance of 10ft., his head striking the stone floor. He is recovering.

Damage to the extent of over £500 was occasioned by a fire which occurred on Saturday at the residence of Mr. Richard Hansom, an architect, in Grove Park-terrace, Ealing.

A receiving order has been granted in the case of James Dolby Belham, trading as S. Belham and Co., of Buckingham Palace-road, S.W., builder and contractor.

The Accrington town council resolved on Monday to purchase the gas and waterworks for £713,220, being 33 years' purchase, subject to an expert's report being satisfactory, and also if the ratepayers approved.

The corporation of Colchester have purchased several meadows close to the centre of the town for the purpose of a public park, and they are now being laid out. Nearly a hundred men are engaged on the work, and it is hoped that it will be completed by the 1st of November. In the excavations which have been made, several Roman remains have been discovered.

The new Church schools, Chester, are being warmed and ventilated throughout by means of Shorland's patent Manchester Grates, and patent Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

A provisional committee interested in the projection for the erection of a new pier at the west end of Morecambe have decided that Mr. Harker, A.R.I.B.A., Manchester, the engineer for the new south pier, Blackpool, together with Mr. Butler, of the Stanningley Ironworks, should be empowered to make a survey of the two suggested sites—opposite Regent-road and the Battery Inn—and to submit approximate estimates of the relative cost to an enlarged committee appointed at the meeting.

A corner plot in Pilgrim-street, Newcastle-on-Tyne, has just been covered with business premises, Renaissance in style, and five stories in height. Mr. James T. Cackett, of Grainger-street, Newcastle, is the architect, and the chief contractor was Mr. John Ferguson, of the same city. Messrs. Ewart, of London, carried out the copper domical roof to the angle turret at the junction of the street façades.

Our Office Table.

IN contributing to a correspondence in the daily papers on the alleged discovery in Russia of some duplicate cartoons by Raffaele, Sir J. C. Robinson, Her Majesty's Surveyor of Pictures, states that these are only copies, executed a century and a half after the originals, and from the tapestries in Rome. He points out that fine series of the tapestries, made at Arras in the 16th century, exist at Ford Abbey, Somerset, now owned by Mr. Herbert Evans, and in the Museum at Berlin; while many other sets and isolated examples, varying greatly in degree of merit, exist elsewhere, as for at least 150 years after the execution of the original series the tapestries were reproduced by manufacturers in every country. Sir John Robinson again offers his protest against the decision of the Parliamentary Commission, appointed last year on his initiative to inquire into the state of the cartoons at South Kensington, to retain them in that institution; he holds strongly that the cartoons should be returned to Hampton Court, as in the smoke-laden atmosphere of London their progressive deterioration is certain.

A new school of applied art in Edinburgh, established under the auspices of H.M. Board of Manufactures for Scotland, for the purpose of imparting to craftsmen a knowledge of art design as applied to industries, will be opened on the 17th October. Some eighteen months ago a number of those directly concerned in the application of art to industries, feeling the necessity of systematic education beyond what can be obtained in the workshop, took the matter up in the hope of doing something "to remedy the present unsatisfactory state of things." What they suggested was a practical development of the instruction given in Edinburgh at the Royal Institution or at the Heriot-Watt College. The Board of Manufactures, whom they approached in the first place, while viewing the project favourably, pointed out that the money at their disposal was barely sufficient for the work they had on hand. The promoters thereupon opened a subscription list, and a sum of about £1,400 was subscribed, to which was added £1,000 contributed by the town council out of the residue grant. The Board of Manufactures have undertaken to manage the classes, and, in anticipation of the opening next month, the joint committee, under whose superintendence the school is conducted, have instructed Dr. Rowand Anderson and Mr. Alexander Inglis, secretary to the Board, to purchase an outfit and acquire examples. For this purpose these gentlemen started on Monday last for London, Paris, and other cities. The basis of the teaching is foreshadowed as "an education in common" in Classic, Renaissance, and Mediæval arts.

The Birmingham Municipal School of Art stands this year at the head of competing schools in the kingdom, having gained a larger number of prizes than any other. Its students have obtained at the National competition two gold, eight silver, and 15 bronze medals, and 27 book prizes, in all 52. Manchester comes second with 48 awards, receiving no gold medal and six silver ones. Glasgow comes third with 23, and South Kensington fourth with 17, but in the latter case it should be noted the students who are in training for art masterpieces do not compete.

VERY bad reports reach us as to professional prospects for architects and the state of the building trades in the Australian colonies. An old and valued correspondent of this journal, who has peculiar facilities for judging of the state of the labour market throughout Australasia, writes us from Sydney: "Things are in a terrible condition over here at the present time—the combined results of unprincipled and 'barm' swindling, the attitude of the labour party and the strikers and the cursed Protection, which even New South Wales has been saddled with for the last six months. A past president of the Victorian Architectural and Engineering Association, on a visit to Sydney, told me the other day, 'In Melbourne we've got no money at all—nobody has: all we can do is to live upon one another, and all we've got to do it with is credit.'"

COMMENTING on the recent protest of the town council against the unsatisfactory state into which the War Office has allowed Stirling Castle to fall, a correspondent of the *Scotsman* says:—"Stirling

Castle is a flagrant case of the effects of official vandalism and pernicious utilitarianism. It has been necessary or convenient to maintain it as a military station, and the ancient buildings have been patched and carved in the most remorseless way to gratify the desire of the War Office authorities to do things on the cheap." The Palace itself, a work of James V., has suffered less than other portions, having been occupied as barracks for nearly a century; but the still older Parliament Hall and the Chapel Royal have been reroofed and are used as a canteen and store-houses. The present Secretary for War, Mr. Campbell-Bannerman, who has been member for the Stirling Burghs for a quarter of a century, ought to signalise his reappointment by rescuing the castle from its present condition of sordid neglect.

THE city council of Liverpool will seek powers next session for a new local Building Act. The measure will provide powers so that, after the passing of the Act, the use of any building as a public building or warehouse building, which was not used for such a purpose before the passing of the Act, shall be deemed to be the erection of a new public building or warehouse building, so as to bring it within the provisions of any act or by-law applicable to new public buildings or warehouse buildings. Also, that any alteration, addition, or other work carried out in any old building, or in any new building after the roof has been covered in, shall, to the extent of such alteration, or addition, or other work, come under the provision of any acts or by-laws in force for the time being within the city. Also, that it shall not be lawful to erect any hoarding or similar structure to be used for advertising purposes, in, or abutting, or adjoining, any street, of a greater height than 15ft. above the level of the street, without the consent of the corporation, subject to certain conditions. The provisions of this clause are only to apply to hoardings forming structures in themselves, and not to hoardings fixed against walls of houses and buildings. Existing hoardings are to be subject to the new provisions after five years. Powers are also sought with regard to sky signs similar to those recently obtained by the London County Council.

If the statistics given in the San Francisco journals, and quoted without comment by the *American Architect* are reliable, the chimney shafts attached to manufactories and foundries do not attain very lofty dimensions in the United States. It is claimed for a shaft now in course of construction for the Edison Electric Light Company in Jessie-street, San Francisco, that it will be "the largest chimney on the Pacific Coast, and the third in point of size in the United States." The total height, however, of this shaft is but 175ft. above the pavement, with a diameter of 18ft. 6in. at the base, and of 14ft. at the cap. Such a flue is but a pigmy as compared with those attached to Thames-side cement works.

At the Railway Congress recently held in St. Petersburg, a statistical table showing the lines open in the different quarters of the world was presented. This table shows that their total length at the beginning of this year was 385,803 miles, of which 167,755 are in the United States, 14,082 miles in Canada, and 5,625 miles in Mexico and the Argentine Republic. In Europe, the German Empire comes first with 26,790 miles, France second with 24,310 miles, Great Britain and Ireland third with 22,685 miles, and Russia fourth with 19,345 miles. In Asia, apart from the 16,875 miles of lines in India, the Transcasian line recently constructed by the Russians is 895 miles in length, the Dutch colonies have 850 miles of railway, the French 65, and the Portuguese 34; while there are 125 miles of lines in China, and 18 in Persia. In Africa, the colonies of Algeria and Tunis come first with 1,940 miles, the Cape Colony second with about 1,880 miles, Egypt third with 965 miles, and Natal fourth with 341 miles; while the Orange Free State has 150 miles, and other minor States about 300 miles. In Australia, the figures are 2,703 miles for Victoria, 2,275 miles for New South Wales, 1,645 miles for Queensland, 1,875 miles for South Australia, 515 miles for West Australia, 401 for Tasmania, and 1,950 for New Zealand.

THE St. Louis Waterworks main conduit is of tunnel-shaped section, with vertical side walls and a semicircular arch of 4½ft. radius, making a 9ft. conduit. The invert is segmental, of granitoid upon a concrete bottom, which concrete extends

on each side of bricks as a backing to the side walls and ducts. The 11ft. conduit is of similar construction. The brickwork is of three rings to the 9ft. conduit, of hard-burned red brick laid in Portland-cement mortar 2 to 5. The concrete backing is made of 2½in. broken limestone, river sand, and Portland cement, in the proportion of 10, 5, and 2, laid and rammed in beds of 6in. thickness.

The Architectural Association.—September 17. Sixth Summer Visit to Loseley Park (by kind permission of Mr. More Molyneux and Gen. Palmer) and Guildford. Train 1.55 p.m. from Waterloo (Central Station). Members will kindly obtain their own tickets. Further particulars may be had of Mr. F. T. W. Goldsmith, 1, Verulam-buildings, Gray's Inn, W.C.

ERNEST S. GALE

Hon. Secs.

Trade News.

WAGES MOVEMENTS.

AMALGAMATED SOCIETY OF CARPENTERS.—In the September issue of the organ of this society, issued on Wednesday, members are requested to keep away from the following places pending a settlement in these towns: Belfast, Dover, Lancaster, Leith, and Waterford. Also to call upon the B.S. before seeking work in Widnes.

THE BUILDING TRADES FEDERATION.—A meeting was held at Wimbledon on Sunday morning, under the auspices of the Federation of Building Trades, Mr. Johnson (Amalgamated Society of Carpenters and Joiners) presided, and the meeting was addressed by Mr. Verden (secretary), Mr. Barnes (Amalgamated Society of Carpenters and Joiners), Mr. Stephenson (general secretary of the United Builders' Labourers), Mr. Hubble (Operative Bricklayers' Society), and others. The necessity for combined effort by workmen in the outlying districts was pointed out in order that the promised advance of wages on November 1 might be carried out. A resolution was carried, calling upon all men engaged in the building trade to join the Federation.

CARDIFF.—The strike in the building trades at Cardiff still continues. The plasterers' delegates have had a conference with the Master Builders' Association, but were unable to come to terms on the questions of piecework and wages. The operative plumbers have met a joint-committee of master builders and plumbers, but without result, the men refusing to accept 8½d. per hour, the maximum offered by the masters. A similar failure attended the bricklayers' conference.

HAWICK.—The operative masons have come out on strike in consequence of the employers having failed to recognise the rules of the Operative Masons' Society of Scotland, a branch of which was recently formed in Hawick.

HOLYWELL.—The joiners have given notice to their employers of a demand for an increase of 2s. per week in wages, and a reduction of 2½ hours per week in hours of labour. The notice expires on the 17th inst., and the men state that they will go out on strike unless their demands are conceded.

NORTHAMPTON.—The bricklayers' strike has been settled, and the men have returned to work, a farthing rise being given at once, and a second farthing, raising the rate to 8d., being promised on and after November 5th next.

A new church, to be dedicated to St. Clement, is about to be built on Banker's Hill at Bradford as a memorial of the late Viscountess Mountgarret, at the cost of her daughter. Mr. E. Prioleau Warren, of London, is the architect, and the outlay will be about £12,000.

A new vicarage and stables have just been built at Verwood, Dorsetshire, at a cost of about £6,600. They have been erected from the designs of Messrs. Adye and Adye, M.M.S.A., of Bradford-on-Avon. The walls are built hollow, and faced with red brick, with Westwood stone dressings. The roofs are covered with dun-coloured tiles. The inside and outside decorations were carried out by Messrs. Cotterell, decorators, Bristol; the gardens were laid out by Messrs. D. Steward and Son, Bourne-mouth; and the contractor for the buildings was Mr. George Moore, of Trowbridge.

A Parliamentary paper relating to Building Societies just issued gives particulars relating to 1,237 societies in England and Wales. Of this number 26 terminated in accordance with their rules, 181 were dissolved under their own rules, 410 were dissolved by instrument, 38 were wound up, 84 were united with other societies, 32 transferred their engagements to other societies, and, with respect to 466, letters addressed to them were returned through the Post Office as "not known," or irregular intimation was sent to the Government office that the society had been dissolved or was abortive.

Holloway's Pills.—The Greatest Wonder of Modern Times.—They correct bile, prevent flatulency, cleanse the liver, and purify the system, renovate the debilitated, strengthen the stomach, invigorate the nerves, promote health, and re-establish the weak to an ardour of feeling never before expected. The same of these Pills throughout the globe astonishes everybody.

DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMLEDITCH STONE is of the same crystalline nature as the Chelynch Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to **CHARLES TRASK and SONS**, Doulting, Shepton Mallet, Somerset. London Agent:—**Mr. E. A. WILLIAMS**, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

THE HAM HILL STONE COMPANY
NORTON, STONE-UNDER-HAM, SOMERSET.
London Agent:—
Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

CRAIGLEITH STONE.

UNEQUALLED for Staircases, Steps, and Landings, especially for Public Buildings with great wear. **VERY HARD, and NEVER WEARS SLIPPERY.**

SOLE AGENTS for England,

J. & A. CREW, Cumberland Market, London, N.W.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with the greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—**T. PETTITT and CO.**, Lithographers, 28, Firth-street, Soho, London, W. Established 50 years.

WM. OLIVER & SONS,

Thomson extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

ALDGATE.—For building warehouse at rear of the Three Nuns Hotel, Aldgate. Mr. R. A. Lewcock, 88, Bishopsgate-street Within, architect:—
Gill Bros. (accepted) ... £1,800 0 0

AUDENSHAW.—For flagging and curbing part of Audenshaw-road, for the Audenshaw Local Board. Mr. J. H. Burton, Ashton-under-Lyne, surveyor:—
Marland, F., Ashton ... £380 0 0
Storer, T., Denton ... 346 0 0
Boardman, A., Higher Openshaw ... 323 3 9
Underwood Bros., Dunkinfield ... 321 9 4
Worthington and Pownall, Manchester 312 13 11
Surveyors' estimate ... 311 10 9
Kinder, H., Hooley-hill (accepted) 308 9 1
Brierley, J., Ashton ... 324 4 2½

BIRMINGHAM.—For the restoration of the ring of ten bells at St. Philip's Church:—
Barwell, J., Birmingham (accepted).

BOURNEMOUTH.—For building National schools in Gladstone-road:—
Hoare, W. (accepted) ... £1,535 0 0

BRIXTON, S.W.—For the erection of a detached residence in Burton-road, Brixton, for Mr. Harry Grover. Mr. M. V. Treleaven, Acre-lane, Brixton, S.W., architect and surveyor:—
Courtney and Fairbairn ... £1,150 0 0
Maxwell (Limited) ... 1,099 0 0
Rice and Son ... 1,075 0 0
Smart and Son ... 900 0 0
Cowper ... 785 0 0

BRIXTON, S.W.—For new roof and lantern-light to warehouse at rear of 148, Brixton-hill, for Mr. Thomas Lighton, Mr. M. V. Treleaven, Acre-lane, Brixton, S.W., architect and surveyor:—
Freight, J. (accepted) ... £104 0 0

BROMLEY, KENT.—For additions of billiard-room, conservatory, kitchen, &c., to Nettlestead, Sundridge-avenue. Mr. Ernest H. Abbott, 6, Warwick-court, High Holborn, W.C., architect. Quantities by Mr. A. Johnson, 50, Imperial-buildings, Ludgate-circus, E.C.:—
Arnaud and Sons ... £1,092 0 0
Hall, Beddall and Co. ... 1,070 0 0
Grady ... 1,040 0 0
Bowyer ... 997 0 0
Crossley ... 995 0 0
Lowe ... 958 0 0

BURY, LANCs.—For painting buildings and railings at the Rochdale-road recreation grounds, for the town council:—
Lomax, J. and S. (accepted).

BURTON-ON-TRENT.—For various works at the maltings, &c., in Park-street, for Messrs. J. Bell and Co., brewers. Mr. R. Stevenson, Imperial Chambers, Burton-on-Trent, architect. Quantities by the architect:—
Hodges, G. ... £193 0 0
Hunter, J. and C. ... 186 5 0
Edwards, H. (accepted) ... 178 0 0
All of Burton-on-Trent.

BURTON-ON-TRENT.—For the erection of a new public-house in Blackpool-street, Burton-on-Trent, for Messrs. Charrington and Co., brewers, Burton-on-Trent, architect. Quantities by the architect:—

Varlow, J. ... £1,420 0 0
Hodges, G. ... 1,379 0 0
Edwards, H. ... 1,360 0 0
Lowe, T., and Sons (accepted) ... 1,350 0 0
All of Burton-on-Trent.

DARLSTON.—For the removal of old cottages in Blackmore's-lane and putting the thoroughfare in order, for the local board:—
Lees (accepted).

DAYBROOK.—For additions to the Daybrook laundry, Daybrook, Notts, for Messrs. Robinson Bros. and Co. Mr. W. H. Higginbottom, King John's Chambers, Nottingham, architect. Quantities by the architect:—

Maule, W. ... £481 0 0
Greaves, J., Arnold ... 467 0 0
Hind, E. ... 459 0 0
Wheatley, J. ... 457 10 0
Vickers, H. ... 457 0 0
Shaw, J. ... 450 0 0
Herring and Jew, Arnold (accepted) 420 3 0
Rest of Nottingham.

HANLEY.—For the erection of a higher grade board school:—

Godwin, T., Hanley (accepted) ... £10,550 0 0
(Lowest of ten tenders received, the highest being £13,102.)

HIGH BARNET.—For alterations and additions to the Red Lion Hotel, High Barnet, for Mr. Sydney Evershed, M.P., brewer, Burton-on-Trent. Mr. R. Stevenson, Imperial Chambers, Burton-on-Trent, architect. Quantities by the architect:—

Marriott, H. J., High Barnet ... £1,550 0 0
Austin, W., West Barnet ... 1,452 0 0
Baughen, J., Barnet ... 1,375 0 0
Pearson, M., Barnet ... 1,325 0 0
Allen, C., and Son, Barnet (accepted) 995 0 0

HOLYHEAD.—For the erection of a county police-station at Holyhead, for the Anglesea police committee:—
Williams, D., Carnarvon ... £3,157 0 0
Williams, W., Holyhead ... 2,769 0 0
Williams, D., Carnarvon ... 2,700 0 0
* Accepted.

VOL. LXIII.—No. 1967.

FRIDAY, SEPTEMBER 16, 1892.

THE MANCHESTER TECHNICAL SCHOOL COMPETITION.

THE designs for the proposed Municipal Technical School, to be erected on a site given by the legatees of the late Sir John Whitworth, Bart., for which the Corporation of Manchester invited architects to compete in April last, have been on view at the Municipal School of Art in Cavendish-street in that city. The instructions issued to competitors required accommodation for thirteen different departments—viz.:—1, Administration; 2, Mechanical Engineering; 3, Applied Physics and Electrical Engineering; 4, Textile Trades; 5, Applied Chemistry; 6, Dyeing and Finishing; 7, Brewing; 8, Metallurgy; 9, Building Trades; 10, Letterpress and Lithographic Printing; 11, Industrial Design; 12, Commercial Subjects; 13, Women's Work. These departments necessitated a large number of rooms in each case, and involved five or six stories. The accommodation asked for in the shape of floor space is very large, and must have entailed much labour in providing for the several departments, especially as they had to be distributed according to the requirements of each science and trade. The rooms were to be easily accessible without passing through one room to another. Those intended as laboratories and workshops and for the machinery had to be provided in reference to the fixtures necessary, some of them requiring—as in the laboratory for testing machines, and for magnetic and electrical experiments—to be placed in the basement. Each department had to be self-contained, arranged with a general eye to supervision, and placed conveniently near other departments; the rooms for students and class-rooms were to be well lighted, with a left-hand light if possible, the rooms and corridors had to intercommunicate, be well lighted, ventilated, and warmed. One main entrance with spacious vestibule leading to a hall for the exhibition of models and other objects, and a staircase leading therefrom to a large hall above, to accommodate 900 persons, were required, besides offices for the administrative department, staircases for students, and lifts, electric lighting, &c.

These various requirements left little room for architectural display, and the elevations submitted with most of the designs show that the competitors had enough to tax their resources in the plan, which left them very little scope for architectural disposition, in many instances the external design exhibiting very commonplace features. In fact, a technical school on a limited site is certainly not a very promising building for the architect's imagination, or one that is suggestive of artistic possibilities. The site at the corner of two main streets—Sackville-street and Whitworth-street—is a quadrangle well adapted to give an imposing building, as it is bounded on the two other sides by Rifle-street and Granby-row. The main angle is rather obtuse; but this irregularity has been avoided by some of the designers setting back the Whitworth-street frontage to a line at right angles to Sackville-street. Many have made the latter street the main front, being the longest; others have adopted Whitworth-street, and the term "rear" would therefore be given to the Rifle-street boundary, which was suggested for the physical laboratory. The approximate superficial area for the departments was given at 144,400sq.ft., and the cost was not to exceed £75,000. The authors

of the first premiated design have cubed their buildings at 6d. a foot, and their estimate is £85,000.

The four designs which have been awarded, and of which we published the authors' names last week, are four of the best as regards plan, but scarcely equal to the artistic ability shown in others not premiated. The design of Messrs. Spalding and Cross, which receives the first premium, has a plan which shows considerable skill and compactness in general grouping; but it lacks in the provision made for the heavy machinery, and the benches for those delicate instruments required in making magnetic and electrical experiments, which require perfect freedom from all vibration and other disturbing causes. For instance, the advanced laboratory is placed on the ground floor facing Granby-row, and is without the means of securing so desirable a condition, the foundations not being shown for the benches. The basement floor would certainly have been the right place for apparatus and fixtures of this kind. We also query the lighting of the spinning room, as shown by the section, the windows being obtained over the weaving-room shed, which is parallel to it. The workshops are lighted through glazed roofs of areas. The authors have not very clearly shown how the shafts and belting are to be arranged for working the machines. The ground-plan forms a double quadrangle divided by a central axial block running from Sackville-street to Rifle-street. This comprises the main entrance and vestibule in Sackville-street, a hall for large objects divided by columns into bays, and at the Rifle-street side a grand staircase with cloak-rooms under. The Sackville-street block, besides the entrance, has the clerks' rooms and committee-room on the left of entrance, and the mechanical laboratory and telegraphy room on the other side. The return block in Whitworth-street is devoted to mechanical engineering, the drawing office being at the corner. The Rifle-street and Granby-row blocks are given to applied physics, having the elementary laboratory in the centre of latter, the advanced at the Rifle-street end, and telegraphy at the Sackville-street corner. Thus the administration is represented by the exhibition hall block in the centre and one half of the Sackville-street block; the Whitworth-street block is given to mechanical engineering; while applied physics comprises the rear and the other two sides of the quadrangle. Towards Whitworth-street the oblique frontage has been utilised by breaking forward the drawing office, at the end and one lecture room. The two internal courts are surrounded by corridors 9ft. wide, which very properly are continued through the blocks for light and ventilation. At each of the four main corners is a block projecting into the area comprising a students' staircase and lavatory, thus giving students immediate access to their departments. The corridors are wide, and lighted from the areas as well as from the end. The entrance hall and museum form a direct communication from main entrance to the main staircase in Rifle-street. On the first floor the lecture and examination hall is placed over the central museum, approached by the main staircase. The administration department occupies the same blocks as below, the building trades are placed along Whitworth and Rifle streets, and the dyeing and finishing department along Granby-row and Sackville-street. The reading-room is over the main entrance, with library and technical instruction rooms in connection. On the second floor the commercial subjects are provided for in front and Granby-row; applied chemistry with lecture-rooms towards Whitworth-street, a gymnasium with dressing-room and kitchen offices, &c. On the third floor over centre hall are the laboratories for qualitative and quantitative analysis, also rooms for industrial design and

metallurgical departments; and on the fourth floor the industrial design and women's departments are accommodated as suggested. The departments are well grouped in the main, and the means of intercommunication and lighting excellent. The author uses red brick and terracotta or stone in the elevations, which show five stories, besides basement half sunk. The conditions are generally complied with. All students would pass the porter's office in front, where they would be registered; the author provides an inclined way to bicycle-room on basement in Sackville-street, and the four staircases for students are available for access to the lecture-hall on first floor. An iron roof is shown over this hall, which is lighted both from the side areas and from roof. The front towards Sackville-street is shown by a forcibly-coloured elevation of red bricks and terracotta, or stone dressings, five stories in height, in addition to basement, in a French Renaissance style. A boldly-tinted India-ink perspective shows gabled angle projections and centre.

The second premiated design, by Messrs. Gibson and Russell, has a more carefully devised basement floor, in which the laboratories and workshops are well grouped. The foundry and weaving and testing shops are parallel to Sackville-street at the Granby-row end of block. Applied physics and electrical engineering occupy the Rifle-street front, the advanced laboratory and mechanical laboratory occupying more than half of this front, and in line with the laboratory and testing room of the mechanical department—a desirable arrangement. The Whitworth-street and Sackville-street fronts have the working and administrative rooms, with gymnasium, &c., in the centre, on one side of a court, 88ft. by 62ft. On the ground floor, the main entrance is placed at the end of Whitworth-street block, next Sackville-street front, and the museum is placed alongside, and extends a considerable distance along this front, with staircase at the end. The administration department is continued along Whitworth-street, the frontage of which is made to square with Sackville-street, with caretaker's house in the acute corner of site outside the main building. An internal corridor gives access to the departments, which comprise the administration, mechanical engineering, physical and textile departments, and are partly lighted by two inner courtyards separated by the elementary laboratory and telegraphy rooms, which form the central cross block. On the next floor the examination hall, 88ft. by 45ft., occupies this position, lighted by the courts on each side, and approached by the staircase from the museum facing Sackville-street. The departments are well kept together. The textile occupies the front and right-hand return, the mechanical department extends round Granby-row and Rifle-street corner, and the administrative and women's department round the remainder of block towards Whitworth-street. The commercial subjects occupy the same wing on the second floor, and the building trades the remainder of three fronts, while the third floor has the industrial design on the Whitworth-street front, and applied chemistry and brewing at the rear of Granby-row. Dyeing and printing are assigned the front block, with metallurgy over the centre. There are five stories and basement. The workshops are covered by an iron roof. The Sackville-street front is extremely plain, having circular-headed wide and oblong windows of factory-like character; the upper floors are relieved by bands of terracotta, and there is an ornamental centre gable with cupola over. The fronts towards Whitworth-street and Granby-row are plain, if not ugly. The ground-floor corridors do not appear to be well lighted. The perspective view is by no means flattering, and there is a heaviness of treatment.

The third premiated design, by Mr. Ernest Runtz and Mr. F. R. Farrow, is of 18th-century Classic character. The main Sackville-street front has a centre and corners with level parapets, without visible roofs, against which the main roof stops. Red brick relieved by bands of light material and arched windows, rusticated, are the chief relief. The Whitworth-street front has a gable in centre over the public entrance, and flat-topped angle pavilions, a domical low story building at corner over lavatory, &c. In plan the authors distribute their Whitworth-street block in line with the street, which makes an unfortunate obtuse-angled junction between the end of it and the Sackville-street block. The exhibition hall is placed on the longitudinal axis parallel to the longer frontages, and is 95ft. by 50ft., divided by columns into aisles. From the end of hall a corridor continues to Granby-row, where there is a student's entrance. There are four areas—two on each side of longitudinal hall block, with corridors running the whole length of the Rifle-street and Sackville-street blocks, joining a transverse corridor along the inner side of Whitworth-street block. Dyeing and finishing occupy the Rifle-street, and the building trades the Sackville-street fronts. There appears to be a want of classification and division of departments; thus we find on the first floors the building trade partly in Whitworth-street, with dyeing, shorthand, and dressmaking on the same floor at corner of Sackville-street. Mechanical engineering is located in the same front, and applied physics and chemistry in Granby-row. The lecture and examination hall is 80ft. by 50ft., and in line with the exhibition hall, from which it is approached by a staircase at the end of latter. The corridors are well lighted by the four areas. The position of the applied physics and electrical engineering on the second floor is undesirable, for reasons we have pointed out, and these departments would have been better in the positions assigned to building trades and dyeing on the ground floor. They are made to occupy the Rifle-street and Granby-row blocks, industrial design being placed along the principal fronts. The general grouping of blocks was capable of a better classification of departments.

The fourth premiated set by Mr. Theodore Sington, of Manchester, shows a cleverly-planned and well-worked-out basement floor, in which the author has evinced considerable technical knowledge of the requirements of the main workshops and laboratories. The laboratory for testing is placed in the Whitworth-street block, which runs parallel to the street; the applied physics and electrical department faces Rifle-street. The advanced laboratory, 50ft. by 30ft., is shown with proper stone benches carried down to the solid rock, with room for constant temperature below it, and the dynamo-room and engine-house complete this range. The moulding-shop and foundry are convenient to the laboratory for testing and metallurgical laboratory. The textile trades are arranged in three departments parallel to Granby-row, and occupy the centre portion of area, all top-lighted. The shafting and belting for working the looms, reeling and other machines, are well arranged. A corridor gives access to these rooms. The ground floor shows the main entrance in Whitworth-street leading to a large hall parallel thereto, with inner corridor, giving access to departments. Applied physics occupies the Rifle-street and Granby-row fronts. The plan is thus a large quadrangle, having a series of parallel glazed roofs over the textile workshops. On the first floor, the mechanical engineering department forms the Rifle-street block, and the building trades that towards Sackville-street, the examination hall being in the Whitworth-street block. The second floor

accommodates the commercial, the women's, printing, and brewing departments; the third floor applied chemistry and dyeing. The external elevations are Italian in style, neatly drawn, with corner pavilion roofs, and a centre arched entrance in Whitworth-street. The Sackville-street front has a centre. There are five stories, and the material is mainly of red brick, and dressings of a lighter material. Generally, the workshop and laboratory accommodation is well provided for; the author simplifies his plan by making his main blocks surround a large open quadrangle, the suites of rooms being made accessible by an inner corridor. Ample light is obtained to the two large halls, but the staircase access, lifts, cloak-rooms, and minor details are scarcely so well provided as in the other designs.

The other twenty-two designs include a few which run the favoured four very closely, both in plan and elevations; these are distinguished by letters. Amongst them we may mention "C" as an elaborate, artistically grouped and well-drawn set of designs having a sepia perspective. The design is Renaissance in character, the main front is towards Whitworth-street, the centre block of which is well emphasised by a high-pitched roof, with lofty flèche; the plan is U-shaped. The corridors are wanting in directness and lighting. "M" has also a well-grouped arrangement of blocks; the main façade is pronounced by a centre flanked by turrets with cupola terminations and gabled ends in a like style and of red brick. There are four areas in plan giving light and ventilation. The examination hall and mechanical lecture rooms are placed on the long axis, and corner staircases and lifts are provided. The front towards Whitworth-street is broken to the line of boundary, a plan which a few others have availed themselves of. "N" is also a design of English Renaissance, with mullioned windows and a gabled front towards Sackville-street. There is a centre entrance and corner pavilions with bay windows, and the Whitworth-street front is well broken, and conforms to the boundary. It is accompanied by a well-drawn perspective in sepia. "U" is designed in the same style. A great octagon angle tower and cupola and a high tiled roof are shown. "W" is well balanced with two courts on the plan. "L" is clever, and the detail shows some playfulness of fancy in the relief ornament. "E" is also marked by originality, with angle turrets and a large circular examination hall in Whitworth-street. Other designs show double quadrangle arrangements, but some of these are laboured, and the corridors are indirect and badly lighted. Amongst these we may name the plan marked "K" and several others. The heavy warehouse style is very conspicuous in many of the designs, as in "J" and "Q"—the latter has six stories. The requirement of height and number of floors has been decidedly prejudicial to an architectural treatment; the piled-up stories too often remind one of blocks of industrial "flats," and it was judicious for this reason to exclude Gothic as a style.

THE ALTERATION OF PREMISES.

IN London and all large towns the practice of turning private dwellings into warehouses, hotels, and public buildings has been very usual. These alterations have been made often with the intention of evading the requirements of the Building Acts, which in the Metropolis impose thicker walls and other conditions. Large tradesmen and manufacturers take the leases of several dwelling-houses, and, by the removal of the party-walls, staircases, and other partitions, they succeed in transforming the several premises into one spacious shop. Sometimes the operations have been so far successfully

concealed from the exterior that important structural alterations have been made without due notice having been given. One mode of proceeding is to open one shop after another, keeping up the appearance of distinct shops under one management. In course of time the party-walls are pierced or removed, girders are inserted to carry upper walls, the staircases are removed, and by slow degrees, under the disguise of "repairs," considerable alterations are made, which convert the premises into huge showrooms, and, as far as habitability goes, "death traps." We have occasionally had to record serious accidents arising out of this mode of conversion, disastrous fires sacrificing human lives, caused by improper construction and want of adequate egress. The evil of turning private into business premises has not yet been stopped. Certain sections of the Metropolitan Building Act, as secs. 22, 27, 28, apply to these alterations, but are not explicit nor comprehensive enough. Thus, the term "public building" is meant to apply to any building used as a church, chapel, college, public hall, hospital, theatre, concert-room, hall, lecture, or exhibition room, and to any such it is required (sect. 22) that the floors and lobbies, corridors, landings, and flights of stairs shall be of stone or other fireproof material, and carried by supports of the same kind; and that the walls, roofs, floors, galleries, and staircases shall be constructed in a manner approved by the district surveyor (sect. 30). Both these clauses are vague, while the latter may mean any construction that is approved. But there are no practical rules for transforming dwelling-houses into large shops, or into lodgings for separate families, or into warehouses of certain size, or into uses other than those of public worship or entertainments—that is to say, the only rules have reference to the area or cubical contents, and therefore, if a manufacturer chooses to convert two houses into a dwelling-house for separate families, and contrives to bring the cubic feet below, even by a foot, the statutory 125,000c.ft. of the 22nd sect., he need not make his floors and corridors or stairs of fireproof material; and also if the limit of 216,000c.ft. was not exceeded, dwelling-houses could be turned into a warehouse without having to conform to the rule as to party-walls. In short, by just keeping within these statutory limits, any one can build as he likes. This in fact is done every day.

We are glad to find that the City Council of Liverpool are seeking powers to obtain a new local building act, which will prevent this obvious frustration of the spirit of the Act, under which it is now customary to convert private buildings into warehouses or public buildings. By this proposal the use of any building as a public or warehouse building not used for such a purpose before the passing of the Act shall be deemed to be the erection of a new public building or warehouse, and so be brought within the provisions of the Act or by-laws applicable to such buildings. Also, it is provided that any alteration or addition carried out in any old building, or any new building after the roof has been covered in, shall, to the extent of such alteration or other work, come within the provisions or by-laws in force. The last provision is very necessary. Alterations and additions are constantly being made to premises in a quiet and unobtrusive manner internally, but which may involve great risks. For example, the putting in of a bressummer for a new shop front to an old house may be executed in a manner that would violate the rules laid down in the local by-laws. The supporting piers, or the bearings, or the section of beam may be insufficient; if a girder be put in to carry a party-wall, there is greater difficulty of proving the workmanship, as was lately discovered in a recent fatal fire at Battersea.

Fig 1

Fig 2

Fig 3

Fig 4.

Again, several brick walls may be removed and wooden partitions be substituted; or a lift or hoist may be constructed without necessary precautions. A hundred things may be done without even the knowledge of the local surveyor, rendering a building not only dangerous in case of fire, but unsafe to the inmates. The London County Council would be setting a good example by introducing clauses in their Consolidation Bill that would control all such alterations and additions.

THE "RENDU" OF ARCHITECTURAL DRAWINGS.—I.

THE study of putting in shadows in drawings has taught us how to determine on the surfaces of bodies exposed to the rays of light, the portions which should be brilliantly lighted and those which remain in actual shadow, and also the position and form of shadows cast against the lighted surfaces by projecting objects or planes. The shadows well indicated in a drawing lend very much to enhance the value of the work; but we must not forget that however well the form of the shadows may be put in, unless the natural effects of colouring, reflected light, and distance are equally well observed, the result will not be what it should be.

The getting-up of architectural drawings, or

the "rendu" as it is called in the Continental art schools, is the art of representing conventionally in colour or neutral tint the various natural effects of brilliancy, tone, and colour in respect to the laws of lighting and distance. We learn the manner in which the rays of direct or reflected light are received by the surfaces of the object, and also the variation of effect with regard to the position of the observer and object, as well as the method of rendering these effects in the drawings by means of colour, Indian ink, or neutral tint.

The rays of light, as in the case of shadows, are supposed to arrive from above at an angle of 45° with the horizontal and vertical planes. The visual rays come direct to the eye of the observer, and all these rays are parallel to each other. Now, besides the direct rays of light at 45° we have the indirect or reflected rays, and these play an important part in the getting-up of a drawing.

If we could imagine an object perfectly isolated in space and receiving the rays of the sun, the portions of the object not influenced by the rays of light would be imperfectly black shadow. But if we place near this object another body, also brilliantly lighted, the lighted particles of the second body would send back the rays, and these, striking the parts of the other body in shadow, would tend to light up to a certain degree these shadows, making them appear less black.

The sources of indirect rays are many, but in

conventional drawings two only are considered necessary to produce the light and shade effects. These two are, the terrestrial rays or light sent back from the surface of the ground, and the atmospherical rays, light reflected from the atmosphere surrounding the object.

Atmospherical rays is the reflection of the direct rays of light by the innumerable particles contained in the air. Each particle floating in the atmosphere acts as a reflector to the direct rays of light, therefore all the particles mutually sending back from one to another these rays in combination produce the indirect diffused light. We, therefore, understand that the shadows of an object such as a building, resting on the ground and surrounded by other objects, are never absolutely black, but always more or less lighted by the indirect rays from the surface of the ground, combined with the indirect rays from the atmosphere.

There are two kinds of indirect rays—those reflected from polished surfaces, and those sent back from unpolished surfaces. A surface in an unpolished state, such as a sheet of unglazed paper, a piece of chalk, &c., appears to be lighted in the same degree of brilliancy all over its surface—no portion will appear to be brighter than the rest. And any change in the position of the object or the observer will not influence to any degree the apparent lighting of the surface. A sheet of iron heated to a red glow is a good example of an unpolished surface. The

light sent back from an unpolished surface is, therefore, diffused—that is to say, the rays are equal to each other in intensity, and do not combine with each other.

If we take an example of a polished body, such as a sheet of polished tin, we shall notice that different portions of the surface appear more or less brilliantly lighted, and each movement of the surface or the observer brings about changes in the apparent lighting. The rays sent back from a polished surface are direct or in a combined state.

We may suppose the surface of the earth to be that of an unpolished body; the light reflected from this surface is, therefore, in a diffused state. An object or building reposing on the ground receives to a greater or less degree the indirect diffused rays from its surface. Therefore, the shadows of the building will be affected by the reflected rays from the surface of the ground.

The general shadows in a building should also for the same reason become lighter in proportion as they approach the ground or reflecting surface, and come under the influence of the indirect rays. Mouldings in shadow turned towards the ground should, for the same reason, be lighter than those turned towards the sky.

We have said that the particles floating in the atmosphere materially reflect the rays of light, and, sending back indirect rays, tend to lighten the shadows of an object. The more we cover these particles and prevent their reflection arriving to the shadow, the darker will this shadow be. Thus the shadow cast by an object against a lighted surface will become darker in proportion to the distance of the object from the surface—that is to say, the nearer the object the darker the shadow, its nearness preventing the action of a certain proportion of the indirect rays. The shadow of A, Fig. 1, will be darker than that of B. The shadow of a chimney against a roof will be darker as it approaches the base of the chimney, Fig. 2. As the distance between the observer and the object increases, so in proportion does the apparent intensity of colour and shadow diminish.

When an object is at a certain distance from us, the rays of light sent back from the object lose their intensity during their voyage through the reflecting particles of the intervening atmosphere. Again, the air between the observer and the object is always more or less charged with impurities and moisture, the effect being to lessen to a great degree the intensity of the reflected rays. In a pure and dry atmosphere, as in Egypt, the colours appear brilliant even at a great distance.

We will take three planes of distance. For the first plane, that nearest the observer, we may consider the effect of distance as nil, and that the colours and shadows retain their utmost degree of intensity. In the second plane, however, the colours begin to combine with the bluish tint of the atmosphere: yellow will appear less yellow and more bluish-yellow; red, less red and more bluish-red; and blue itself less blue if originally dark blue, or more blue if originally light blue. In the third plane these effects are more accentuated. In the far distance the bluish effect greatly increases, and all the colours melt more or less into blue: yellow takes a greenish tint; red, nearly violet; and blue, light blue if originally dark blue, or dark blue if originally light blue. But this blue should never surpass or contain more colour than the blue of the sky, which is the blue of the atmosphere at its greatest intensity.

We will shortly endeavour to render in neutral tint these various effects of distance.

We have also to take into account the effects of contrast and irradiation. We know that if two surfaces, one coloured black and one white, are placed together, the white appears whiter and the black blacker by the effect of contrast; and in two surfaces of an equal size, the white appears larger than the black; in fact, the light colours seem to encroach on the dark colours. This may be noticed when looking at a window strongly lighted from behind—the dark window-bars appear narrower than they really are. A grey surface against white appears still more grey, and black against grey makes the grey appear almost white. Again, colours appear more intense when placed near their complementary colours. Two tints of green slightly different will mutually diminish the effect of one another; but the same green against red appears all the more intense. The same effect will be

noticed with all colours and their complementary colours. If we placed any bright colour against white, the white will gradually appear to be tinted with the complementary colour.

All these effects should be introduced when necessary in an architectural drawing, and should be even exaggerated—the drawing will then appear effective. Of course, the student must combine method with taste, and a close study of natural effects. The windows of a building appear very dark, for the interior of a building is naturally less lighted than the exterior. The dark of the window should also contrast with the well-lighted wall-surface. The roofs of a building appear dark, so as to be well detached from the brilliantly-lighted sky. The shadows in a roof should appear very dark. The general tint of a building should gradually become more intense as it approaches the top; and the portions against the sky should appear tinted with orange, the complimentary colour of the blue of the sky. Therefore buildings of yellow stone or red brick should be graduated in colour, the tint being more intense near the top, and slightly coloured with orange or yellow against the sky.

Fig. 3 is an example of the effect of contrast, the surface B in shadow becoming gradually darker in tone as it approaches the lighted surface A. In Fig. 4, the upper portion in shadow F should appear darker than the rest of the shadow, it being in contrast with the sky. The fine shadows of small mouldings, as at D, should appear very dark, and much darker than the large surface of shadow at G.

A SANITARY CRUSADE THROUGH THE EAST AND AUSTRALASIA.—III.

(Continued from page 347.)

MR. BOYLE was very cordially received by the Melbourne architects, many of whom he had met before when he first visited Australia seventeen years ago.

Melbourne may justly be considered the most remarkable city in the world, the site it occupies being little more than fifty years ago nothing but dense bush, the only sounds heard being the shrill call of the aboriginal and the howl of the dingo. Now there exists a handsome city having a population of nearly half a million, with magnificent public and business buildings which would compare favourably with those of any capital in Europe.

The streets, especially Collins-street and Bourke-street, are wide, well paved, and kept scrupulously clean, whilst the system of cable cars in use is the most complete in the world.

The Houses of Parliament, which are of Classic design and commanding situated at the head of Bourke-street, constitute the most striking architectural feature of the city. Three air-pump ventilators 9ft. in diameter, the largest ever made, were applied to this building about seventeen years ago, and proved very successful, as testified to by the report of the Minister of Public Works and Railways, the Honourable John Woods, M.P. Within the last few years two other systems have been applied for the purpose of mechanically forcing air into the buildings.

The first was introduced by Mr. Lloyd Tayler, F.R.I.B.A., a leading architect in Melbourne; but before the work could be completed and properly tested a change in the Ministry occurred, when it was decided to adopt another plan which, though an improvement on the old method of admitting air, which consisted of plain open tubes, has not proved entirely successful, there being strong complaints of down-draught.

Mr. Boyle was desired by the Honourable Gavan Duffy, M.P., chairman of the Ventilation Commission, to make an examination of the present ventilating arrangements of the House, and furnish a report thereon and a plan for the improvement of the ventilation embracing the latest improved form of the self-acting air pump ventilator, which has been done. The present ventilators in the roof, intended for the exit of the air, and which consist of the old louvre pattern and plain open pipes with covers on their tops to prevent the ingress of rain, when tested by Mr. Boyle and the engineer, were found to be admitting a strong down-draught of cold air effectually preventing the egress of the vitiated air. This down-draught was also experienced on the floor of the House when the plenum system was in full operation. The arrangements for washing, cooling, and warming the air-supply were also found to be defective.

Mr. Lloyd Tayler, who is a scientific expert in ventilation and an accepted authority on the subject, has adopted the air-pump ventilator for the new Commercial Bank now in course of erection in Collins-street, and which, when finished, will rank with the finest buildings of its kind in the City. Mr. Tayler writes Mr. Boyle: "It will give me great pleasure to avail myself of your well-known patent ventilators in the various buildings with the erection of which I may from time to time be intrusted." During Mr. Boyle's stay in Melbourne he received very valuable assistance from Mr. George C. Inskip, F.R.I.B.A., the President of the Royal Victorian Institute of Architects, who says:—"I am pleased that you propose establishing a manufactory of your patent ventilators in this colony. I shall be glad to specify your ventilators, and will do so." Mr. Boyle, in conjunction with Mr. A. Purchase, F.R.I.B.A., surveyed the new Stock Exchange, a very handsome building situated in Collins-street, and prepared plans for the ventilation, which will be made on a very elaborate scale. An examination was also made of the Bank of Victoria and other buildings, and plans for the ventilation submitted. Messrs. Oakden, Addison, and Kemp, architects, state:—"We believe your patent ventilators will meet all requirements, and shall be glad to specify them." Messrs. Crouch and Wilson also report:—"The system of ventilation formulated by you has always commended itself to us as the only means to secure absolute automatic and efficient ventilation." This is endorsed by Messrs. Craven, Brown, and Marquand, who say:—"We have had frequent opportunity of proving the value of your inventions."

A system of sewerage has now been adopted for Melbourne, and is in course of construction, the initial cost of which will be about three millions sterling. Mr. Thwaites, the engineer-in-chief to the Melbourne Metropolitan Board, conferred with Mr. Boyle on the question of the ventilation, and instructed him to prepare and submit a complete scheme of ventilation for the sewers and drains on the Boyle system, which has been done. It is also proposed to adopt the air-pump ventilators for the ventilation of the soil-pipes. Messrs. John Danks and Son, Limited, Melbourne, have been appointed agents for Victoria.

At Adelaide the Houses of Parliament, Government House, Government Buildings, Supreme Courts, Post-Office, Museum, Art Gallery, University, the Hospital, and a large number of other public buildings are ventilated with the air-pump ventilators.

After visiting Tasmania, the "Garden of Australasia," Mr. Boyle proceeded to New Zealand, arriving in Dunedin, the chief town in the province of Otago, having a population of 46,000. There are a number of handsome public buildings in this city, where Mr. Boyle found his ventilating appliances in general use. Messrs. Mason and Wales, architects to the hospitals, report: "Your ventilating cowls have been used on several buildings designed by us with good effect."

Christchurch, or, as it is called, "The City of the Plains," situated on the banks of the Avon, is eminently English in its appearance, architecture, and surroundings, and has a population of 45,000. The house-drainage of this town is, in accordance with the drainage regulations, ventilated exclusively with the air-pump ventilator, and it is estimated that there are over 5,000 used for this purpose in Christchurch alone.

Mr. Edwin Cuthbert, C.E., engineer to the drainage board, the highest sanitary authority in New Zealand, reports: "It gives me much pleasure to state that I have used your air-pump ventilators in connection with the house-drains of this city and district for the last ten years, and I have always found them to act most satisfactorily."

Most of the public buildings in Christchurch are also ventilated with the Boyle system. Mr. J. C. Maddison, F.R.I.B.A., states: "I have for years specified Boyle's ventilators, and shall insist upon them always being used, as I consider them the best"; whilst Mr. F. Strouts writes: "I always specify the air-pump ventilators, and they have always acted most satisfactorily."

Messrs. Taylor and Oakley, Christchurch, have been appointed agents for the South Island of New Zealand. Wellington, the premier city of New Zealand, the seat of Government and the Vice-Regal Court, is beautifully

HOUSES OF PARLIAMENT, MELBOURNE.

situated at the south end of the North Island, and has a population of about 34,000. It possesses many handsome public buildings, including the Houses of Parliament, Government House, Government Buildings (said to be the largest wooden structure in the world), Post Office, Supreme Courts, Hospital, Opera House, &c., to all of which the air-pump ventilators are applied. Mr. W. Hales, the Government Engineer-in-Chief, reports: "The ventilating

board, who writes: "I have known for many years the form of construction of your excellent ventilating appliances, and it gives me much pleasure to learn that you have established in the Colonies a method by which we can obtain ventilators of your latest pattern." A very handsome building of Early English design, intended as an insurance office, is at present in course of erection near to the post office, the ventilation of which will be effected by six large air-pump

Thomas Ballinger has been appointed agent for the provinces of Wellington, Taranaki, and Napier. Auckland, the mother town and first capital of New Zealand, is a very fine city, having a population of 52,000. It possesses a number of handsome public buildings, many of which are ventilated with the Boyle system. Mr. Chas. R. Vickerman, C.E., President Government Engineer, writes: "I am very pleased to learn that you intend to give us the benefit of your ex-

MUNICIPAL BUILDINGS AND CENTENNIAL HALL, SYDNEY.—(See p. 347.)

appliances manufactured by your firm have been used in many of the Government buildings in this colony, and have given perfect satisfaction." The air-pump ventilators are also employed for the ventilation of the soil-pipes, several thousands of them being in use.

It is proposed to rearrange the drainage system of Wellington, and Mr. Boyle has submitted a scheme for the ventilation on the Boyle system to Mr. William Ferguson, chairman of the drainage board, and engineer to the harbour

ventilators of an ornamental character. The architects, Messrs. Clere and Richmond, report: "We have occasion very frequently to use your ventilators, which fulfil all the requirements of a good exhaust ventilator."

Messrs. Thomas Turnbull (F.R.I.B.A.) and Son, who were among the first to adopt the Boyle system in New Zealand, state: "We have great pleasure in testifying to the excellence of your Air-Pump Ventilators, which we have always found to act most satisfactorily." Mr.

cellent ventilators in this city. I shall take every opportunity of availing myself of your deservedly-popular ventilators."

In the Colonies, as in this country, architects have occasionally inferior imitations of the air-pump ventilator, &c., supplied by unscrupulous contractors in place of the genuine articles which were specified to be used, and respecting which disreputable practices Messrs. Boyle have received a large number of letters from architects and others.

to the width, being equal to a whole circle from the stage, and that the straight lines narrowing towards the scene have a disagreeable aspect, and some of the disadvantages which would attend the sides if they were square. In

FIG. 2.

comparing these disadvantages, it is necessary to observe that our attention is constantly engaged by the actor; that we maybe content with looking once or twice at a scene, but our face is always towards the actor, therefore those side seats which approach the stage look in a direct line; but as they recede from the stage, the angle becomes proportionably acute, and occasions a very painful position of the head.

The circle is not a suitable form for a theatre except on the private-box system, as the seats

FIG. 3.

converge to the centre of the auditorium instead of to the centre of the stage. Fig. 3 shows an arrangement of a horse-shoe form for a small theatre, with the sides planned for private boxes. The seats should not be sighted to only one point on the stage, for this reason, as already fully described in a former chapter. The dress-circle

FIG. 4.

seats should be arranged on a slight curve facing the stage, and the sides (Fig. 4), as is almost universally the case, given up for private boxes for those who care to be seen, more than to see.

There are, however, cases in smaller theatres where private boxes are deemed necessary for the legitimate use of witnessing the performance; these are then placed, as at the Gaiety and Princess's, behind the rows of the dress-circle seats.

Where a theatre has two or more tiers rising one above the other, the arrangement of the various circle fronts on the same line or curve is monotonous, besides being prejudicial to seeing, hearing, ventilation, and the comfort of the audience. The arrangement of lines may be somewhat on the system of the accompanying diagram, or any other variety of curve that the architect may desire (Fig. 5). Where the various lines meet at the commencement of the side private boxes, it may be generally accepted that the horseshoe form, with its modifications, is appropriate for the large opera houses, but a semi-elliptical curve is best for the small theatre.

Mr. Ralph Neville, who is a strong advocate for the Haymarket plan, calls attention to the fact that there is a large class of intelligent playgoers, who now rarely attend theatres, as they cannot afford, or grudge, more than a half-crown, and are not prepared to face the discomfort of the ordinary pit. It is this class who are benefited by the first circle, which has taken the place, in point of price, of the defunct pit at the Haymarket. This circle, as is well known, is at a level slightly higher than the dress circle at most theatres, and is a most excellent position from which to view the performance. With regard to the ceilings over the circles or over hanging galleries, Mr. Neville advises that they should, where possible, be slightly curved—it is seldom, however, the cantilevers will permit this—and that they should be always coloured blue, which is the colour giving the effect of distance.

It will be within the recollection of some of my readers that a few years back there was published in the *Daily Telegraph* the plan and section of a scheme for the construction of what was termed a "safe theatre," which, it stated, "Mr. Henry Irving has conceived, and Mr. Alfred Darbyshire, architect, of Manchester, has developed." The diagrams (Fig. 6) and the published description of this scheme almost demand their

FIG. 5.

reproduction in this series of articles, as they have been recently referred to by Mr. Townsend, in his paper on "American Theatres," read before the Royal Institute of British Architects during the past session. For this reason I give the following extract:—"As the building would be only one story high, the question at once presents itself—how is it intended to dispose of the various sections of the audience? The answer involves a complete revolution in the internal arrangement of our theatres. The lofty gallery will disappear, to find a more comfortable, more convenient, and more healthful location upon the ground floor immediately behind the pit, while in front of the latter, as at present, there will be the stalls. Although the "gallery" will thus be placed at a distance from the stage, its frequenters will have a thoroughly good view of the scene, and will be able to see the faces and expressions of all the artists, instead of gazing down on the top of their heads. This is secured by keeping the dress circle overhead sufficiently high and sufficiently far back to allow the persons in the most distant seat of the gallery to be in the line of sight with the stage, so that they will command from one to two-

thirds of the area of the proscenium. The single story of the theatre is devoted to the dress and upper circles, which are reached by straight staircases, communicating directly with the street, and attaining no more at their utmost height than 24ft. from the ground. The facility of access and egress thus provided seems all that could be desired, both in point of extent and directness. There are four public exits from this part of the house opening upon the street by means of straight distinct staircases, without landings or curved steps of any kind. There are no openings to any staircases, except the direct one from the auditorium. If the safety of the patrons of the theatre has been consulted at every point, it has been done without sacrifice to their pleasure. Indeed, in the proposed building their command of the stage would be greater than at present; the seats are all arranged in the segments of a circle, and are divided longitudinally and transversely by gangways 3ft. wide. From the above plan, it will be seen that the upper circle and dress circle have each an entrance and an exit staircase on opposite sides of the building. Corresponding provision is made for the reception and departure of the audience on the ground floor by means of an entrance and an exit on each side of the house. At the close of the performance every night all the entrance doors will be converted into exits, so that practically the outlets would on all occasions be doubled, as on all occasions they are to be used—the latter an important consideration, since in case of panic there would be no unfamiliarity with the provisions designed for speedy and safe escape, and no crush by conflicting crowds meeting on a common staircase or entrance hall. A house of this simple form would allow of a more perfect system of ventilation than is now practicable. Nor would the multiplicity of passages tend to the discomfort of the audience by creating draughts, as all the doors would be made to close automatically, thus arresting any currents that might be created, while at the same time the provisions for liberating the spectators would remain unimpaired, all the doors being made to open outwardly upon the application of the slightest pressure."

I will not comment upon the internal arrangement of the audience in this "safe theatre," further than to say that at a distance of 90ft. 8in., which is the depth of the auditorium, the unfortunate occupants of the back row of the gallery would have little chance to see the facial expression of the actor or hear the words he uttered. I leave for the present any observations on planning of the exits and staircases in this scheme, as I shall have to deal with this in a future chapter.

CHIPS.

The new pavilion in connection with the bowling green at Whitefield, near Rochdale, was opened on Saturday. The pavilion consists of a billiard-room 32ft. by 21ft., reading-room, committee-room, bar, lavatory, and other suitable accommodation. The architect is Mr. Thomas Thorp, of Whitefield.

Memorial stones of a new Wesleyan chapel at Fillongley were laid by Lord Leigh on Wednesday week. It is Gothic in style, and is to be built of brick with stone facings; it will seat 150 persons, and adjoining is a schoolroom accommodating 75 children. Mr. Ewan Harper, of Birmingham, is the architect, and Mr. W. Hopkins of the same city is the builder. The outlay will be £900.

Mr. J. Buchan, A.M.I.C.E., at present borough surveyor of Grimsby, has been elected city surveyor by the Norwich corporation.

The highway bridge at Charlton, Dover, has just been rebuilt and widened for the corporation of that town. Mr. W. Bromley was the contractor.

The South Shields School Board have appointed Mr. William Landler assessor in a competition for a new school, and have instructed him to advise them as to the conditions of competition.

In the bankruptcy case of Alfred James Ingram, of Maud-grove, King's-road, Chelsea, and late of Ellison-road, Streatham, late builder, and now of no occupation, the discharge has been suspended for two years, ending August 8, 1894.

At the Saffron Walden petty sessions last week, a man giving the name of Joseph Gregory was committed for trial on a charge of forging the name of Mr. Joseph Bell, J.P., builder and contractor, to a cheque for £12 10s. Prisoner is alleged to have asked Mr. Bell, as a magistrate, to attest a signature to some papers, and then to have copied the name as an endorsement to a cheque.

THE BUILDING NEWS DIRECTORY.

Below we publish a BUILDING NEWS DIRECTORY, to which Architects may easily refer when in search of the makers and vendors of Architectural and Building Specialities.

The large Advertiser is, of course, to a considerable extent independent of such help. By his judicious iteration of the merits of his specialities he effectually impresses the mind of the constant reader with his claims to attention. But he will find it to his interest to avail himself of our new help to publicity; and besides, there are hundreds of Manufacturers who never advertise in the ordinary way, or who, if they do so, only advertise one or a few of the articles they make and supply, and who yet

essentially need constantly to remind Architects of their existence.

It may be urged that the Trade Directories and Price Books to a certain degree supply this want; but when it is remembered how limited, comparatively, is their circulation, and how swamped the comparatively few that are wanted are for the most part amongst hundreds of thousands of other names and addresses in which Architects have no interest, and among which they are seldom likely to search for what they require, it will be seen at once how advantageous in a Journal like THE BUILDING NEWS will be the introduction of the feature we contemplate.

It will be evident, of course, that many Manufacturers will desire to have more than one

entry in the list, because they supply more than one speciality. For the majority possibly one entry will be ample, and that we undertake to make and to repeat weekly in every edition for the sum of ONE POUND PER ANNUM, payable strictly in advance, and expiring on the 31st of December in each year.

Clients who may desire to have more than one entry under different heads can do so to any extent they please by payment of *One Pound each* for every additional entry.

All payments must be made in advance, as this feature is not introduced as a remunerative one to the Publisher in itself, and the small charge made will barely defray expenses, and will not allow of booking.

A few spaces are open in the Directory for 1893. To secure insertion, orders should be sent on EARLY. Renewals for 1893 should also be sent early. We cannot guarantee insertion for any that do not reach us by Dec. 1.

AIR PUMP VENTILATORS—

BOYLE, ROBERT, and SON, Ltd., 64, Holborn Viaduct, London; and 110, Bothwell-street, Glasgow.

ANAGLYPTA—

WOOLLAWS, W., and Co. (Private Designs), High-street, Manchester-square, London, W.

ARCHITECTURAL DESIGNERS—

FINEBURY TRACING and DRAWING OFFICE, 113, Pavement, E.C.
MARK FOSTER and Co., 110, London Wall, E.C.

ARCHITECTURAL METAL WORKERS—

BRAVYN, THOS., and Co., 64, Clement-street, Birmingham.

ARCHITECTURAL PHOTOGRAPHERS—

BEDFORD, LEMERS, and Co., 147, Strand, London, W.C.

ARCHITECTURAL TERRACOTTA—

GIBBS and CANNING, LTD., Tamworth.

ARTISTIC WALL PAPERS—

JEFFREY and Co. (Non-Arsenical), 64, Essex-road, Islington, N.
WOOLLAWS, W., and Co. (Free from Arsenic), High-street, Manchester-square, London, W.

ARTISTS IN STAINED GLASS—

BOURNE SWAINE, 61, King Edward-road, Birmingham.
EVANS, CHAS., and Co., 20, Warwick-street, Regent-street, London, W.
JENNINGS, J., 118, Clapham-road, London, S.W.

ASPHALTE—

ATELIERE SCILIAN ASPHALTE. JOSEPH BERNAYS, 96, Newgate-street, E.C.

BATHS, PUBLIC—

BRADFORD, THOS., and Co., Crescent Ironworks, Salford, Manchester; and 140, to 143, High Holborn, London.

BATH STONE—

BATH STONE FIRMS, LIMITED, Bath.

BLINDS—

WILLIAMS, G. A., and SON, Queen's-road, Bayswater.

BOOKS—

B. T. BATESFORD (Professional), 53, High Holborn, London, W.C.
CROSBY LOCKWOOD & SON (Architectural, Engineering, & Technical), 7, Stationers' Hall-court, Ludgate-hill London, E.C.
WHITTAKER and Co. (Practical and Technical), 2, White Hart-street, Paternoster-square, London, E.C.

BRICKS—

ACCRINGTON BRICK and TILE Co. (Facing Bricks, Plastic and Semi-Plastic), 8, St. James-street, Accrington.
GIBBS and CANNING, LTD. (White Glazed), Tamworth.
HEATHER BRICK and TERRACOTTA Co., near Ashby-de-la-Zouch.
POULTON and SON (Red Rubbers and Facings), Ornamental Brick and Terra Cotta Works, Reading.

THOMERSON, CHAS., 263 and 265, Hackney-road, N.E.

THE INTERNATIONAL HORTICULTURAL EXHIBITION, EARL'S COURT, LONDON, S.W.

A GRAND INTERNATIONAL POTATO EXHIBITION

Will be held by the Executive of the International Horticultural Exhibition, in connection with the
SHOW OF HARDY FRUIT, at Earl's Court, London, S.W., on October 5, 6, and 7, 1892.
When PRIZES to the amount of £100 will be offered, also a GOLD MEDAL for the most meritorious
Collection of Potatoes, and a SILVER MEDAL for the best dish of Potatoes in the Exhibition.

Applications for Schedules and full particulars should be made to THE SECRETARY, International Horticultural
Exhibition, Earl's Court, London, S.W., or to P. MCKINLAY, 24, Upper Thames Street, London, E.C.

PATIO DE LA CASA DE OLEZA, PALMA, MALLORCA.—A MINSTREL OF MALLORCA.—HOUSE AT BIRKDALE.—NEW WORKHOUSE, HASTINGS.—NEW WING, OSBORNE HOUSE, ISLE OF WIGHT.—NEW PULPIT AND CHOIR STALLS, ST. MICHAEL'S, BEDFORD PARK.—FURNITURE FOR THE NEW COUNCIL CHAMBER, YORK.

Our Illustrations.

SKETCHES IN MALLORCA, BY W. F. YEAMES, R.A.

ONE of the special charms of the picturesque town of Palma are the numerous courtyards, not two of which are alike. The earliest are Gothic in character; then many in Renaissance style; others a strange mixture of the two preceding manners; and the more recent ones, though attractive, with no distinguishing architectural features. Every house of any kind of pretension has a courtyard, which you enter from the narrow street by a large gateway. One, two, three, or all four sides of the yard are arcaded, and invariably a stone staircase leads to the upper floor, no second floor existing above it. The columns supporting the arches, often of Brescia marble quarried in the island, are squat and bulgy in shape, with capitals generally too large. The arches have a wide and flatish span, giving to the newcomer the impression of weakness, specially as in the view given of the yard of the Casa de Oleza; the arch supports two columns, which in their turn support the flat roof that shelters the staircase. Nowhere in these Majorcan courtyards do you come across pure style or fine proportion; still, the effect produced is pleasant, from its having a character of its own, and eminently pictorial in aspect, several suggesting scenes such as Paul Veronese delighted in. In most of these yards are wells, with elaborate ironwork. The well serves to draw water from a tank underneath the yard, and supplied with water by an aqueduct still in use, and built by the Moors, which aqueduct brings beautifully clear water from a spring in the mountains nine miles off. The different doors in the yards lead to the stables, cellars, and store-rooms, and in many shrubs and flowers are placed in pots about the yard, on the steps of the staircase, and along the open passage above the arch, where, in the Casa de Oleza, tressi-work is painted. Our illustrations are reproduced from the charming paintings by Mr. W. F. Yeames, R.A., shown in this year's Royal Academy exhibition.

HOUSE AT BIRKDALE.

This house is built of 2½ in. Ruabon bricks with red sandstone dressings, the roofs are covered with brown tiles, and the tile-hanging is of red tiles; the gables are modelled in fibrous plaster. The interior finishings and doors are of oak, mahogany, rosewood, and ash, and the floors are laid in the same woods. The ceilings are richly panelled, and the finishings generally are of the best of their kind throughout. Messrs. Duxfield Bros., of Southport, are the builders, and Mr. Frank W. Mee, of 100, King-street, Manchester, is the architect.

HASTINGS NEW WORKHOUSE.

MR. P. H. TREE, F.R.I.B.A., architect, of St. Leonard's, was selected in the competition held some little time ago for this work, and we illustrate the workhouse to-day as developed in the working drawings subsequently prepared. The slope of the site giving a considerable fall necessitates a series of terraces; but the divergence in levels has been cleverly managed. To the rear of the official block, near the entrance gateway, are located the workshops, and between the main group of buildings and the infirmary is placed the workhouse chapel. In the distance is seen the water-tower, and behind the infirmary comes the isolated block.

NEW WING, OSBORNE HOUSE.

We fully described this important new addition to the Queen's marine residence at Osborne, on page 266, in our issue of August 19. The work has been completed from the designs and under the superintendence of Mr. J. R. Mann, A.M.I.C.E., surveyor of works to the Osborne Estate, by Messrs. W. Cubitt and Co. The interior ornamentation of the Indian or Durbar room is being done by Messrs. Geo. Jackson and Son, of 49, Rathbone-place, W., and is exceedingly elaborate, and was designed by Bhairam Singh, of Lahore, and we hope soon to illustrate his work.

NEW PULPIT, ST. MICHAEL'S, CHISWICK.

THIS church is now closed, and will be reopened on Michaelmas Day. The completion of the fabric is in hand, the north aisle being erected and opened into the nave. A new ceiling is in course of erection in the south aisle, and the church is being repainted throughout. The roof and walls between the timbers, which are greenish blue, will be finished a warm yellow cream, and the remainder of the plastered walls are coloured a decided red. The panelled dado round the building is being completed, including a screen, lobby to the north door, and pediments to the vestry and east entrances. Messrs. Adamson and Sons, of Turnham Green, are the builders. The oak pulpit to be erected on the south side of the roof screen illustrated to-day will take the place of the temporary rostrum. The stalls in the choir will not be erected at present, waiting for funds. The sketch explains itself. The pulpit-base is of stone. Messrs. Farmer and Brindley are the contractors for these fittings. Mr. Maurice B. Adams, F.R.I.B.A., is the architect.

FITTINGS IN NEW COUNCIL CHAMBER, YORK.

WE give two more pages of illustrations of the interior fittings of the new Council chamber at York. As stated last week, when we gave the first two pages, the fittings are carried out in white oak, wax polished, and with gun-metal fittings. The work has been executed by Messrs. Oldham and Knight, of Nottingham, from the design of Mr. Gilbert S. Doughty, architect, of the same city.

GRAND HOTEL, CLACTON-ON-SEA.

The illustration published by us last week showed a perspective view of the south angle of the proposed Grand Hotel, Clacton-on-Sea. The reproduction was from the competition set of drawings sent in by Messrs. Roger Smith, Son, and Gale, to whom the first premium was awarded. The work will be carried out by Mr. Arthur F. Gale, F.R.I.B.A., of 4, Serjeants' Inn, Fleet-street, E.C. The site is surrounded on all sides by roads, and when completed the hotel will cover the whole area. The principal front is to the Marine Parade, and will be 160ft. from the edge of the cliff. At present it is proposed to provide bedroom accommodation for 60 guests. Part of the larger scheme provides a hall, arranged so that it can be used for entertainments, either in connection with the hotel or be let apart from it. The structure will be of red brick and stone, and the floors are proposed to be fireproof throughout. The completed block will form three sides of a quadrangle, the centre of which will be laid out as a flower-garden and tennis-court. The estimated cost of the first portion to be built, which alone was illustrated, is about £12,000, exclusive of the cost of site.

An altar-piece of seven panels, containing subjects in the life of Christ, painted by the late Gambier Parry, of Higham Court, has been placed in the Chapter-house of Gloucester Cathedral.

COMPETITIONS.

ACCRINGTON.—In an open competition for new technical schools at Accrington, the designs of Messrs. Morley and Woodhouse, architects, of Bradford, have been awarded the first premium.

WALSALL NEW TOWN HALL.—The corporation have decided to appoint a professional assessor to adjudicate upon these plans when received, but the selection of assessor is not yet made. He will undoubtedly be a gentleman of standing in the profession—so the town clerk says.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION AND THE MUNICIPAL SCHOOL OF ART.—The council of this association have recently issued circulars to the members, intimating that they have completed arrangements with the School of Art by which the educational work of the association will be brought into connection with the school in such a manner as will give greater facilities for the study of architecture. The School of Art and the Architectural Association have combined to undertake a special course of architectural classes and lectures for the purpose of giving a student in four years all that he needs in the early years of his career, the historical subjects being dealt with at the School of Art, and the technical subjects at the association meetings. Special lectures have been arranged for in addition to the classes already held at the School of Art, and the association meetings have been rearranged and strengthened as far as possible. The classes commenced on Monday last. The association, in addition to paying a part of the fees of those of its members who join the School of Art course, affords them the advantages of its own meetings, and offers special prizes both for sessional work and for sketching, &c., during the summer. The lecturers at the School of Art upon strictly architectural subjects are Messrs. W. H. Bidlake, Freeman Smith, and Charles Morgan. At the special meetings in connection with the Architectural Association the subject of construction will be dealt with at gatherings held at Mr. H. R. Lloyd's office, Colmore-row; while a class of design will meet at Mr. W. Hale's, also in Colmore-row.

CHIPS.

Among the resolutions passed by the Trades Union Congress at its final meeting at Glasgow, on Saturday, was one instructing the Parliamentary Committee to take the necessary steps for having passed into law a Bill providing for the compulsory adoption of the Artisans' Dwellings Act by all local authorities.

The local board for Wardle, near Rochdale, have appointed Mr. Tertius Wood as engineer of the sewerage works in succession to Mr. R. Vawser, of Salford, deceased. The terms agreed upon were 2½ per cent. for preparing the plans, and 4 per cent. for superintending the work and getting out quantities.

On Saturday a commodious hall and club, erected by the members of the Leeds District of the King-ston Unity of Oddfellows, was opened by Col. North. The building is situated in Union-street, Leeds, immediately facing the open square known as the "Midden." It is in the Renaissance style. In the basement is a kitchen, in addition to cellars, A billiard-room, containing two tables, and a reading-room, measuring about 26ft. by 18ft., occupy the ground floor. On the first floor is the hall, measuring 53ft. by 25ft., and fitted with a platform, dressing-rooms, &c. The caretaker's premises are located on the second floor, and in addition there are three lodge-rooms, about 21ft. by 14ft. The work has been carried out by Mr. D. Foster, contractor, of Leeds, under the supervision of the society's architect, Mr. J. M. Porter. The cost, including fittings, is £3,500.

The Stockport Town Council have appointed a committee to inquire into the probable cost of erecting a Town Hall for the borough.

Plans have been prepared by Mr. Hubert Bensted, of Maidstone, for the erection of a school of art in part of the museum grounds in that town. The design provides for a new west wing on the site of the curator's garden.

The alterations and repairs of Linlithgow Palace, carried out by Mr. R. Philip, under the direction of Mr. W. W. Robertson, of H.M. Office of Works, are now completed. According to the terms of the Government grant, further repairs will be made next season, when a fountain also will be erected in the grounds.

WAYSIDE NOTES.

A GREAT discovery has been made during the progress of some alterations at the parish church of Long Clawson, a village between Melton Mowbray and Grantham. It was scarcely architectural in the ordinary acceptance of the term, though eminently so in a sense, seeing that the builders of the find in question are old-established architects and contractors of high repute, besides being also geometricians of no mean order. Their style of architecture antedates any other.

The discovery made was a large quantity of honey. Whilst taking down the west wall of the church the workmen came upon a "comb" measuring 5ft. in length, and 2ft. in width. It is supposed, I read, that the west end of the church has been inhabited by bees for more than 25 years, as during the whole of that time they have been seen in the vicinity, and not infrequently have been observed inside the church during Divine service. I trust that we shall not take to pulling down our old churches to find stores of honey; for I cannot help thinking of Charles Lamb's Chinaman who set a fashion of burning down houses in order to provide a plentiful supply of roasted pig.

Somebody has been despoiling—in theory—the interior of the renowned church of Wiggenshall St. Mary's. An assertion that the stalls, screen, and lectern had been purloined by certain parties has been shown to be false by correspondents of the *Athenaeum*. The articles in question being safe, we may leave the wordy war to the wagers thereof; but in the letter of Mr. E. M. Beloe, F.S.A., I was interested to read that until 30 years ago the chancel of St. Mary's retained the old Puritan arrangement of seats all round the walls, and the Communion-table in the centre of the chancel. I see, however, that Bloxham, on "The Internal Arrangement of Churches after the Reformation," notes the fact that "in the chancel of St. Mary the Virgin, Wiggenshall, Norfolk, the old Puritanical arrangement is still kept up, the Communion-table being brought out into the chancel with seats all round." My much beloved author gives, as will be perhaps remembered, an illustration of the Communion-table at Langley Chapel, Salop, where the same arrangement is found, or was to be found, some thirty years back.

A note of more than usual interest appeared in the last number of the *Athenaeum*. It is worth reproduction. Says the writer:—"It is the fashion of a certain class of amateurs in architecture to ascribe to the artisan of the Middle Ages those designs for noble buildings which, in their execution, have, since their time, enchanted the world. Architects proper know better, and point to numerous proofs to the contrary, which demonstrate that, except, perhaps, rude instances where prevailing types have been followed without scruple, it is manifest that a system analogous to the modern one obtained in all important cases. We cited the other day an example, where it is recorded that a patron of the 14th century, who was desirous of building on a considerable scale, sent for a monk of Worcester, who designed and superintended the work for him. The incised slabs at Rouen commemorate two now nameless worthies, and show one of them holding a pair of compasses in one hand, and in the other an elaborate design for the tracery of a window. It is obvious from the costumes that these were not artisans. The "Sketch-Book" of Willars de Honcourt, which was published in facsimile by Professor Willis, attests that he was, in the modern sense of the term, an architect of the 13th or 14th century. Street produces several proofs, derived from the bench tables of certain buildings, that they were built from designs proper, and not according to rules of thumb." Here the writer quotes the well-known lines in "Henry IV., Act I. Scene ii., commencing, "When we mean to build," as further proof in the same direction, and remarks that "as architecture in Shakespeare's time was much less difficult, complex, and, above all, scientific than it had been during the Middle Ages, so much less was the latter likely to have been due to rules of thumb."

This line of argument is pleasing at this day when so many hasten to show that an architect should be a craftsman in a smock-frock, an

artisan with a short "clay," a master mason with his nose at the banker, and anything else except himself. Whereas, as our writer endeavours to prove, an architect was an architect in the olden times as well as at the present day. What pleasure or amusement anyone can find in trying to prove otherwise it is not easy to understand.

It will be a pity, from an artistic point of view, if the Emanuel Hospital at Westminster is destroyed. The old hospital has always appeared picturesque to me, and we do not find many examples of this particular class of building in London. That it affords scope for the artist's pencil may be seen from the illustration of the old institution by Mr. Herbert Railton that appeared a week ago in the *Illustrated London News*.

An amusing incident, and one that surely could only have occurred in our glorious profession, happened during the publication of some correspondence relative to the Emanuel Hospital in the columns of the *Times*. "The Purchaser's Architect" writes about the possible future of the building, when lo and behold! another gentleman, giving his own name, says that he thought that he was the "purchaser's architect"! This was edifying, truly. I trust that the rival purchaser's architects came to some understanding in the matter, and that no third party came forward with still further claim to the title—and the prospective job.

Mr. Railton, with his usual prolific industry, having just finished the illustrations of a large work on the Inns of Court, is about to proceed to execute a commission to furnish the illustrations for a series of articles on "Cloister Life in the time of Richard Cœur de Lion." The articles will appear in *Good Words*, and should prove unusually attractive to architects, as no draughtsman is so competent to deal with such a subject as Mr. Railton.

Information on Norwegian churches would be welcomed by all, as Mr. Harry Hems says. There have been so many excursion steamers to the "Land of the Midnight Sun" that there should be some sketches or photographs of new subjects forthcoming. I fancied the other day, as I passed a photographer's shop, that this effect had really been produced, as I saw many photos of Norwegian scenery and buildings.

I trust the attention of the Building Acts Committee of the L.C.C. has been called to the case of a man who, when brought before the police magistrate at Lambeth on Friday on a paltry charge of defrauding a railway company, successfully posed as the district surveyor for South Lambeth and part of Camberwell. It is due to Mr. Henry Parsons, the district surveyor in question, that he should have the opportunity afforded him of proving that this was an impudent case of personation. Mr. Parsons has held this lucrative district surveyorship since 1853, and it is due to his character and position to show that the man fined for an offence so mean and paltry wrongfully assumed his name, status, and address. Doubtless the builders of his district will avail themselves of an opportunity to raise a testimonial to a much-maligned official, to take the form, say, of a free railway pass. The difficulty in this rectification will be that even Mr. Biron, the stipendiary (who ought to know a district surveyor as well as he does the local police inspector) was imposed upon, for he professed to recognise the defendant as a public official, adding that he had formed a very high opinion of his integrity. By the way, the culprit got off very lightly. If the railway officials are to be believed, the defendant had travelled unchallenged and without a ticket for nearly five years. Now the cost of a first season between Waterloo and Shepperton is £22 a year: 22 x 5 = £110, whereas the pseudo-Parsons was only called on to pay £14 5s., including costs.

I was a little puzzled a few morning ago by the announcement on the newspaper posters of "Nelson's Flagship, Latest," but soon remembered that there was a proposal to destroy the *Foudroyant*. Apropos of this, the *Standard* gave some interesting particulars of other famous vessels. The student of naval architecture should regard these old vessels with reverence, even if they fall short of imitation of the

old craft as architects copy old buildings. The *Shannon*, it appears, which fought and captured the *Chesapeake*, was broken up at Chatham, part of the hull being sold at a fancy price. Sir Francis Drake's *Golden Hind* came to a similar end at Deptford, a chair made of her timbers being one of the treasures of Oxford University. The *Resolute*, which went in search of Sir John Franklin, and, after being abandoned in an ice waste, was picked up by an American whaler, and returned refitted by the United States Government to this country, was moored in the Medway for some years afterwards, but ultimately taken into dock and pulled to pieces, a suite of furniture fashioned from her oaken timbers being sent as a memento to the American President. The *Sovereign of the Seas*, the first British three-decker, built in the time of Charles I., "to the glory of the English nation and not to be paralleled in the whole Christian world," was accidentally destroyed by fire at Chatham after seeing much and long service. Of Captain Cook's *Endeavour* not a trace is left, though several of his scientific instruments have been preserved, nor is there any trace of the *Victoria*, which made the first voyage round the world. Several English and foreign war ships which have been sold to the Norwegians are now carrying timber from port to port. GOTH.

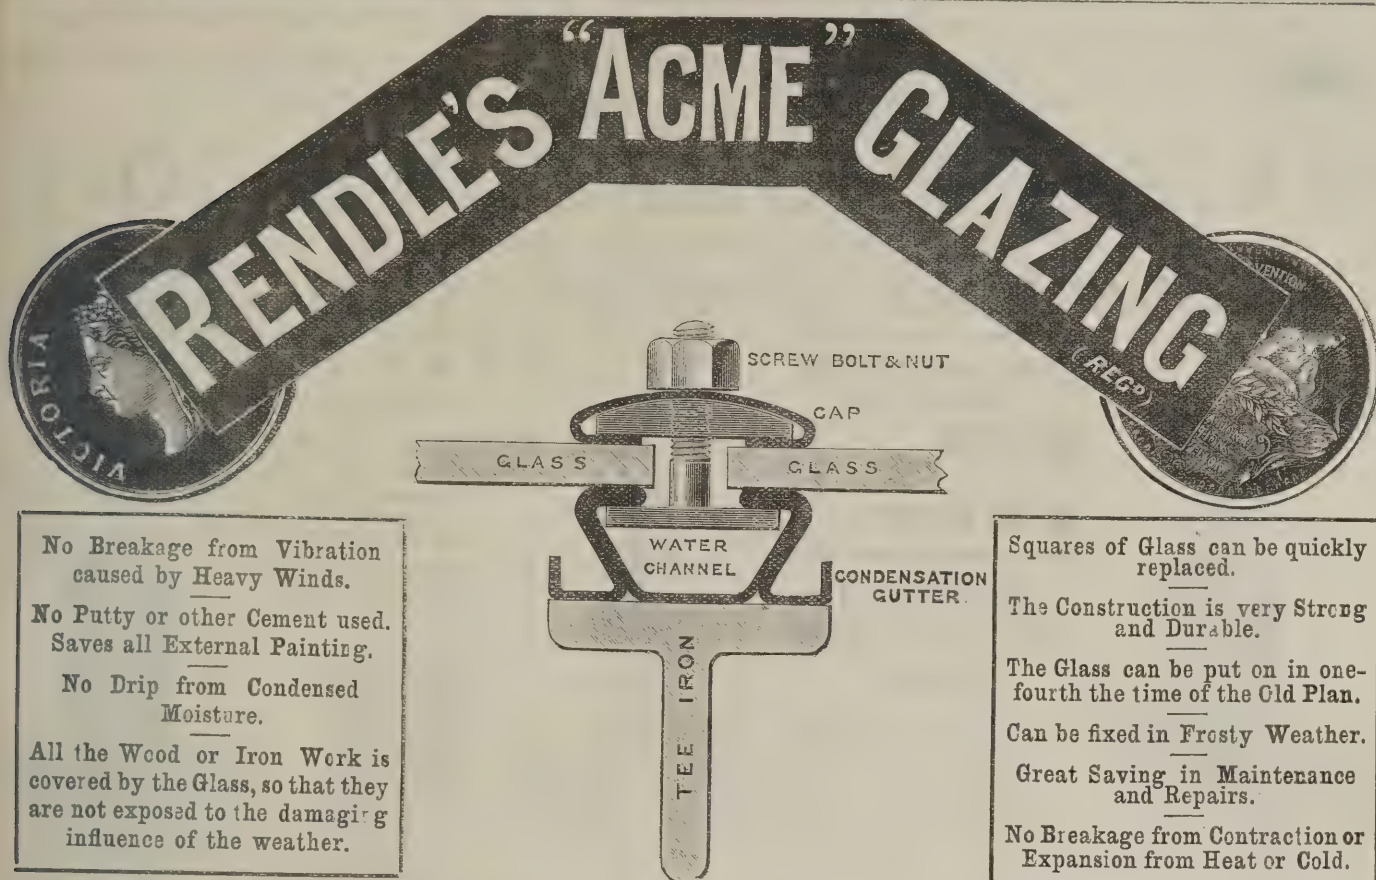

OBITUARY.

THE death is announced of Mr. Joseph Moore, of Birmingham, the well-known medallion and die sinker. Mr. Moore, who was in his 76th year, was apprenticed to Thomas Halliday, a die-sinker who then had workshops in Newhall-street. In conjunction with a fellow apprentice—Mr. John Allen—Mr. Moore entered into manufacturing business in Great Hampton-row, where, under the style of Allen and Moore, the firm largely made engraved metal cups, vases, and boxes. These wares were engine-cut, on bodies coated with colour, and portions being cut away by the lathe, the patterns, chiefly designed by Mr. Moore, were left in colour in low relief. The firm also engaged in the manufacture of papier-mâché ware. Owing to changes of fashion, the enterprise of Messrs. Allen and Moore failed to attain permanent success, the works were closed, and Mr. Moore, having lost all he had, began business for himself as a die-sinker. Most of his work was executed "for the trade." Commissions for medals, portrait medals, commemorative medals, prize medals, not only for Britain, but for the colonies, were intrusted to trading firms; they came to Mr. Moore often for the designs, and always for the execution of the work. Though Mr. Moore employed other artist workmen in his business, the finest of his works were cut from first to last by his own hand. He had a keen appreciation of pictorial and musical art; he was one of the founders and the first president of the Midland Art Club.

Eugène Gonon, the Parisian founder, known to specialists all over the world for his success in casting in bronze by a modification of the *cire perdue* method, which he kept secret to the end, died on Tuesday. The knowledge of this famous process was inherited from his father, Honoré Gonon, and was perfected and continued by Eugène Gonon during more than half a century. Donou and Rodin and other sculptors intrusted to him their work; but he leaves no heir, nor, indeed, a pupil trained in his school. The State a long time ago bought the secret, but it took no pains to utilise it. "His life," says one writer, "which he devoted to the mission of rendering in bronze in the most faithful manner possible the masterpieces of some of his contemporaries, was a rare and remarkable example."

The local board of Bromley, Kent, had 174 applicants for the post of surveyor, recently rendered vacant. They have elected Mr. S. Hawkins, an engineer now in the South-Eastern Railway Company's service.

The old church of Prestonkirk, East Lothian, was reopened on Sunday after extensive alteration in its interior. The fabric consists of a fine chancel of the 13th century, nave of the 17th century, and a quaint tower of unknown date. The alterations that have taken place consist of a perforation of the western wall, opening into the vestry, arching and screening the whole wall with a carved and panelled screen of wood, entire repainting of the church and seating, enriching of the windows, and minor improvements.

RENDLE'S "ACME" GLAZING

Labels in diagram: SCREW BOLT & NUT, CAP, GLASS, WATER CHANNEL, CONDENSATION GUTTER, TEE IRON.

No Breakage from Vibration caused by Heavy Winds.

No Putty or other Cement used. Saves all External Painting.

No Drip from Condensed Moisture.

All the Wood or Iron Work is covered by the Glass, so that they are not exposed to the damaging influence of the weather.

Squares of Glass can be quickly replaced.

The Construction is very Strong and Durable.

The Glass can be put on in one-fourth the time of the Old Plan.

Can be fixed in Frosty Weather.

Great Saving in Maintenance and Repairs.

No Breakage from Contraction or Expansion from Heat or Cold.

Illustrated Catalogue and Book of Designs can be obtained post free from the Inventors and Patentees,

WM. EDGCUMBE RENDLE & CO., 5, VICTORIA STREET, LONDON, S.W.
ENGLISH MECHANIC & WORLD OF SCIENCE.

Price 2d. Post Free 2½d.

A NEW VOLUME COMMENCED AUGUST 26, WITH No. 1431.

In it, and Nos. 1432 and 1433, will be found a Series of Articles on

HYPNOTISM and MESMERISM.

BY

MRS. ANNIE BESANT, F.T.S.

In which many new and interesting facts connected with the latest developments of Occultism are described, and mystic forces generally fully dealt with.

London : 332, Strand, W.C.; and all Newsmen and Bookstalls.

"B. T. & CO.'S Latest Improved Exhaust Ventilator is destined to supersede all other Automatic Ventilators."

 **HIGHEST AWARDS** for Improved Ventilators, 1887-88-89-90-91-92.
Two Grand Diplomas of Honour and 14 Gold Prize Medals.

BAIRD, THOMPSON & CO.'S

LATEST IMPROVED PATENT

SELF-ACTING EXHAUST VENTILATOR.

The most Powerful
Exhaust and
CHEAPEST
VENTILATOR
IN THE MARKET.

**IMPERVIOUS TO

and Consulting Engineers.
165, QUEEN VICTORIA ST., LONDON, E.C.; & 24, BATH ST., GLASGOW.

estimates the cost of an entire preservation at about £450.

The Sussex Archaeological Society, at a general meeting, were "of opinion that every effort should be made to secure the preservation of so interesting an example as the Old Vicarage House of Alfriston"; "with this opinion the Society for the Protection of Ancient Buildings cordially agrees, and for the way of sustaining the building thinks that the general report of the architect, Mr. Owen Fleming, of July 25th, 1892, is based on the right lines."

As soon as funds are forthcoming, and before further outlay, steps will be taken to arrange with the patron and Bishop to secure the building to the parish for ever, as a reading-room and for other parochial uses.

Subscriptions and donations will be thankfully received by the bankers, Messrs. Molineux, Lewes; by the treasurer, Major Molineux, Old Bank, Lewes; or by the Vicar, the Rev. F. W. Beynon, Alfriston Vicarage, Berwick, Sussex.

Cheques, postal orders, or post-office orders should be crossed "Old Bank, Lewes, Alfriston Old Clergy House Preservation Fund." All remittances will be publicly acknowledged.

I most earnestly appeal to all lovers of old work to help me to preserve from destruction this interesting relic of former days.—I am, &c.,

F. W. BEYNON, Vicar.

Alfriston Vicarage, Berwick, Sussex, Sept. 15.

INCOMBUSTIBLE CONSTRUCTION.

SIR,—Having freely experimented with a view to render buildings fireproof—where the risks are great—in as inexpensive a way as possible, I read with much interest the article under above heading which appeared in your last issue. There is no doubt that hollow wooden studded partitions, or match-board lining, to walls with a space behind, such as are largely used in City warehouses, must inevitably, by means of the induced draught, carry the fire from one story to another. If the space between match-boarding and wall be filled in with an incombustible material, the risks of fire spreading would be minimised, and, in fact, there could be but little chance of perfect combustion. Experiments made with silicate cotton prove that it is almost impossible to burn down any structure lined at the back with that material, and this is simply from the fact that when the wood carbonises it offers resistance to the influences of extreme heat, and unless sufficient oxygen can be obtained between the wood and the lining, there is no chance of consuming it. My experience, based on practical experiments, is perfectly consistent with that expressed in your article—viz., that hollow spaces, or rather, spaces between studded partitions and walls, should be done away with or filled up so as to prevent the spread of fire by the induced draught to which I have referred. By filling up any space with silicate cotton, the oxygen is only retained in finely bisected air-spaces, and without this element in full volume, combustion is quite impossible. I have seen a wooden door lined with silicate cotton withstand greater heat than a double iron "fireproof" party-wall door, simply because the lining at back of the wood so effectually prevented the heat from penetrating, that, for all practical purposes, it might have been used as a door again, whilst the iron doors, subjected to the same degree of heat, become totally useless. Buildings used either as warehouses, dwelling-houses, or offices, could undoubtedly be rendered completely fireproof in a simple and inexpensive manner.—I am, &c.,

FREDK. M. H. JONES.

Mr. James Coles, master builder, of Kimberley, South Africa, was recently killed by the fall of some scaffolding on a building in progress. He was a son of Mr. James Coles, of Burnham, Somerset, and had been in business as a builder and contractor in Kimberley about ten years; some of the largest stores in the town were built by him.

The foundation-stone of a Technical School and Free Public Library for Leigh was on Saturday laid by the Hon. John Powys. Mr. Marsh, chairman of the Leigh Science and Art Classes, explained that the number of students was now so large that the present provision was totally inadequate. The building would cost over £10,000, of which £6,500 had been subscribed by the public, and the remainder by the local board.

Intercommunication.

QUESTIONS.

[10848].—**Books for Student Surveyors.**—I have just article a boy to a surveyor and valuer—an all-round country man of good standing, with a fair auctioneer's business. I want the boy to pass the successive examinations at the Surveyors' Institution, with the view of settling him ultimately in some such position as his master's—say, not a genius, but steady and plodding. What are the best books to supply him with as he goes along, and what else can I do to facilitate his improvement?—KAPPA.

[10849].—**Swedish Wooden Houses.**—Can any of your readers inform me what are distinctive features and advantages of Swedish wooden houses? I have seen a description of them in a non-professional paper, and should be glad to learn if they can be rendered reasonably fireproof by means of layers of asbestos. I should also be glad to know (approximately) what saving per cent. would be effected on the cost of building in brick in a town where bricks are fairly cheap? Briefly, is it a practical method of building for such purposes as vestries, meeting-rooms, &c.?—ALPHA.

[10850].—**National Competition Drawings.**—Will any readers give me any information regarding drawings in building construction for the National Competition, such as the scale that they are drawn at and the style of colouring, if coloured, or if done in black and white, and if a perspective view is required?—APPRENTICE ARCHITECT.

[10851].—**Bedding Iron and Wood on Stone.**—When the end of an iron joist or girder has to rest upon a stone template, is anything necessary between the iron and stone besides a bedding of mortar or cement? The writer had supposed a piece of sheet-lead was the proper material to use, until reading an article in the *Building News* for May 6, in which it is stated that experiments showed a great reduction of the crushing strength of stone by using lead, the reason being the lateral flow of the lead under the great pressure. Thin pieces of soft pine, it is stated, were still more destructive of strength. Will friends kindly give opinions as to the best way of placing the ends of iron joists or girders; also heavy wood bressummers on hard stone templates?—J. H.

[10852].—**Tidal River Bath.**—I should be glad if any correspondent would give me the correct internal diameter of a pipe necessary to fill a bath holding 240,000 gals. of water, which has to be taken from a tidal river that will flow over and cover the pipe for one hour. The pipe is covered its entire depth for the whole period, as a small coarse-gravel filter will be built to the level of top of pipe at intake. The greatest head of water will be 4ft.; but by that time water in bath should be level with—TIDAL WATER.

[10853].—**Durability of Cast-Iron Pipes.**—I should like to know if any authenticated records are to be obtained as to the durability of cast-iron water-pipes laid on soil. How many years have pipes so laid been known to last, and what soil is the best?—CONTRACTOR.

[10854].—**Laboratories.**—In a school in which technical instruction is to be carried on, and magnetic experiments made, certain benches are required which shall be free from vibration. Of what material should these benches be made, and what precautions are necessary in their construction? Perhaps one of your many practical readers who have built physical laboratories could favour with some particulars.—ENQUIRER.

[10855].—**State of Boiler and Hot-Water Pipes.**—Will any experienced reader oblige by saying how the condition and safety of a boiler fixed at the back of an ordinary kitchen can be ascertained? During a brisk fire in the latter a loud and explosive noise takes place in the upper hot-water cistern fixed in bath room, and this continues several seconds, and recurs at intervals. The noise proceeds evidently from the bubbles of steam which burst against the top of cistern, which is of wrought galvanised iron. I think it is caused by the reduction of the flow-pipes by incrustation; am I right? Any information as to testing condition of pipes and boiler would be of value.—HOUSEHOLDER.

[10856].—**Folkstone.**—I shall be obliged if any one who knows the neighbourhood will give the names of any old buildings, churches, &c., within reasonable distance.—TOURIST.

REPLIES.

[10833].—**Timber and its Position.**—The reason for placing staves inversely to their natural direction in the tree is because the sap-valves open upwards from the root, and when thus reversed they prevent the ascent of moisture in the wood. I hope this explanation will remove the doubt from the mind of "Philos."—SIDNEY F. HARRIS.

[10842].—**Composition for Renovating Stone-work.**—Try "Fluate," a process discovered by M. Kessler, and largely used on the Continent, the material being supplied by the Bath Stone Firms, Limited. The company supply small quantities, and give instructions. The process prevents decay and arrests disintegration. For Bath and all limestones the process has been found effectual; it is chemical in action, and the resulting products are insoluble. The "fluate" is applied liquid in one or two solutions; it enters the stone and solidifies, and is unaffected by the atmosphere and acids. Before using, all loose and decayed parts of the stone must be removed by a stiff brush and the walls cleaned down, but quite dry. It is applied by a flat brush and produces an effervescence; when this ceases, the application is sufficient.—G. H. G.

A committee has been chosen at Halifax with a view of carrying out a scheme of electric tramways in the town, on the same system as that adopted at Bradford. Messrs. Utley and Gray, conjointly with Mr. Holroyd Smith, are acting as engineers and surveyors for the Halifax scheme.

Legal.

THE LAW OF BUILDING SOCIETIES.

BUILDING societies are just now having a very bad time, owing to the great fall in the value of land and house property during recent years. This is, however, only one cause of the failures which have lately been so common, and others must be sought in the reckless way of paying high interest upon deposits to bring in large sums of money that could not possibly be safely invested again at paying profits. Hence we have had some big crashes amongst those concerns, and shall probably see some more before long. In the meantime, the rules of law and of practice applicable to building societies, whether in their working or their winding up, become more generally interesting and important. For this reason we may welcome the issue of a second revised and enlarged edition of Mr. Wurtzburg's "Law of Building Societies" (Stevens and Sons, Ltd., Chancery-lane, price 14s.) It should at once be stated that though this is technically termed a second edition, because the same author published the Building Society Acts with notes, it is really an entirely new book, having been wholly re-written as a treatise upon this important subject. It is now in a fair way to become the standing textbook and leading authority upon the law of building societies. The work, indeed, has been done very well and thoroughly; it brings all questions and the latest authorities down to date; it contains, besides all the statutes, various useful precedents of rules, mortgages, and deeds, and it is so clearly written as to be quite readable even by those who are not lawyers.

Like most good ideas, that of a building society has fallen upon evil days by being wrongly applied in practice. The original notion was simply the creation of a common fund by subscribers, out of which some were to obtain advances upon thoroughly sound security. As long as a building society kept within the scope of that definition it could come to no harm, and so such concerns acquired a reputation for safety. Then they grew and got bigger. Depositors came in with their money at high rates of interest, which had to be put out at still higher rates. This could only be done by lending much closer to the value of the property offered, and by lending to everyone who became a nominal shareholder for that purpose. In came the artistic and speculative builder. Surveyors were weak, or worse. Directors and secretaries wanted more business, so did the solicitors. Then from being a building society the concern became a company, doing a big pushing trade in doubtful mortgages, and with a general fall of property, and a few large losses from insolvent builders, such a society was shaken to its frail foundations, and ready to fall at any moment of undue pressure. And so many are now falling to pieces accordingly.

FRED WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

Z. O. M.—**DRAINS.—CONNECTION.**—Unless some right of way or water is created by the deeds, I do not consider that A is legally bound to allow C to come upon his land for the purpose of connecting the drains. This would be more clear if there is any written acknowledgment as to the rent paid formerly for permission to do so.

J. H. C.—**BUILDING.—PARTY-WALL.**—I consider the upper portion of this wall is not a party-wall, but a wall built upon another wall below, and therefore entitled to support. Neither does it seem clear that the wall it is sought to pull down is itself a party-wall, for by the sketch there seem to be two distinct walls side by side. The only safe way to proceed seems to me to shore up the adjoining dwellings.

INFRA DIG.—**ARCHITECT.—EXTRAS.**—It may depend upon what the contract says as to extras, but if it left the extras, in the sole discretion of the architect, then his certificate would be final between all parties, and it would not be inquired into except for fraud on his part; still it might be wiser to give an account.

J. H. W.—**DILAPIDATIONS.—SURVEY.**—No, I do not consider that any valuer's license is required by an architect and surveyor, or in relation to such work upon property.

At West Derby parish church, Liverpool, on Friday, a new organ, built by Messrs. Gray and Davidson, of Liverpool, was opened. It contains 244 pipes and 40 stops.

LEGAL INTELLIGENCE.

A DISTRICT SURVEYOR FINED FOR DEFRAUDING A RAILWAY COMPANY.—At Lambeth on Friday Henry Parsons, of Shakespeare-road, Herne-hill, and Hampton Wick, appeared to answer four summonses, taken out by the London and South-Western Railway Company, for having travelled on June 29 last and other days, without having previously paid his fare, with intent to defraud. Mr. Horace Avery prosecuted, and said the defendant was the district surveyor for South Lambeth and part of Camberwell. It was alleged that for years past he had been travelling on the railway without taking any ticket at all. He was formerly a season-ticket holder, and the last of such tickets he held, between Waterloo and Shepperton, expired in October, 1887. Ever since October, 1887, he appeared to have been in the habit of travelling daily between Hampton Wick and Waterloo, usually getting out at Vauxhall, but occasionally travelling from Hampton Wick to Loughborough Junction. During the whole of this time he passed the collectors at both places as a season-ticket holder, and had never been challenged owing to the position he was known to occupy. A number of railway officials in the employ of the South-Western and Chatham and Dover Companies having been called in support of the summonses, the defendant, in reply, said he had been a season-ticket holder for a number of years, and had got into the habit of walking past the collector without giving up his ticket. He found he was losing money by a season-ticket as he travelled very little during the winter, and he therefore took return tickets. On the day mentioned in the summons he had not time to get his ticket, and offered to pay his fare at the other end. It was absurd to say that a man of his character and reputation would be guilty of so paltry an offence. Mr. Biron said he deeply regretted to say that he had come to a different conclusion. He had no doubt that for years past the defendant had been travelling without a ticket, availing himself of his position to pass as a season-ticket holder, and thus to defraud the company. He said this with the greatest possible regret, because he had known the defendant as a public official, and had held a very high opinion of his integrity. He ordered the defendant to pay a fine of 40s. and £5 5s. costs on each of two summonses, the two other summonses being withdrawn.

RE ALFRED KINGABY.—Under the failure of this debtor, a builder and decorator, carrying on business in High-road, Lower Clapton, a summary of accounts has been issued, the liabilities being returned at £1,375, and net assets £49 10s.

CARPENTERS SUED FOR BREACH OF CONTRACT.—At the Hereford Police-court, last week, John Smith, wheelwright, and Arthur Pugh, carpenter, were summoned by Messrs. Johnson Bros. for £1 9s. each for breach of contract. Arthur Johnson, of the firm of Johnson Bros., contractors, of Queen-street, Cardiff, said he saw both men on the 20th August at the yard of Messrs. W. P. Lewis and Co., builders, Hereford. He engaged Pugh for a week, to rough-board the roof of a malt-kin at Chepstow. There was nothing unusual in the job. He engaged Pugh at 7½d. an hour, which was above the average rate, and paid him 2s. 6d. for his week's lodgings, and 4s. 6d., the amount of the single railway fare. Smith subsequently came and said he would go, and was also paid his railway fare. Plaintiff heard from the foreman that the defendants had refused to do the work, and had been given their railway fares to return. In cross-examination, the plaintiff said that it was not true that the work was of a dangerous nature, or that any accidents had taken place on the roof, and that the amount claimed would not cover the amount of the loss occasioned by the defendants' breach of the contract.—William Ganderton, foreman to Messrs. W. P. Lewis and Co., corroborated, and other witnesses said the work was not dangerous. The defence was that the roof was dangerous, and that defendants had not been warned of its character. Defendants' counsel quoted "Chitty on Contracts," to the effect that where there had been a fraudulent misrepresentation or concealment of a material fact, the contract was voidable.—The chairman said that there was no sort of concealment of a material fact as to the difficult nature of the work. The Bench gave judgment for the plaintiffs for the full amount claimed, and costs.

In connection with the Salvation Army at Sheffield, the foundation-stones of a new citadel, which is about to be erected on a site near the town hall, were laid on Monday. The building, which will cost £17,000, will contain an assembly hall with accommodation for 2,000 persons.

At Friday's meeting of the city council of Coventry it was agreed to proceed with the restoration of the north window of St. Mary's Hall, at an estimated cost of £629. That this is desirable is evident from the statement of Alderman C. J. Hill, who said that some of the kings represented had their legs under their arms, and one man had part of a castle in the pit of his stomach.

WATER SUPPLY AND SANITARY MATTERS.

LLANDAFF.—The city of Llandaff, which is in the district of the Cardiff rural sanitary authority, will, in a few weeks, be supplied with water from the Cardiff Corporation's new waterworks in Breconshire. A few years ago all the wells in the city were closed by the sanitary authority, and since then houses have been supplied with water for drinking purposes by water-vans from a reservoir on a lower level, which has been a constant source of annoyance to the inhabitants and anxiety to the officers of the rural authority. The city is drained on the intermittent downward filtration system, which works well. All the manholes are air-tight, and the whole system of sewers are ventilated by three ventilating shafts, situated about three-quarters of a mile apart. One of these, 40ft. in height, was built of masonry in 1886 by the late Mr. Waring, C.E., of Cardiff. In 1889, Mr. Fraser, Assoc. M.Inst.C.E., surveyor to the sanitary authority, ascertained that this shaft was not only inadequate, but very expensive, owing to the enormous quantity of coal-gas required to raise the temperature within a masonry shaft 2ft. square inside sufficient for the ventilation of the sewers, even a short distance away. He therefore designed and erected two cast-iron columns, each 12in. in diameter at base, and 20ft. high, fitted with two Bunsen gas-burners, surmounted by a concave plate a few inches from the burners, which is kept at a red heat by a reduced flame from one of the burners, consuming the sewer-gas as it is extracted from the mains by the strong current caused by the high temperature of the column. These shafts answer the purpose admirably, being both economical and effective, having cost £35 each, fixed complete, and an annual cost of under £10 for gas, and each column will ventilate sewers for a radius of half a mile. This ancient city, with its noble piles of historic buildings and beautiful cathedral, has been very much neglected up to a few years ago, and the present more satisfactory state is the outcome of an intelligent sanitary authority, guided by their energetic officers.

LONG EATON WATERWORKS.—The opening ceremony of these works took place on Thursday week. The supply is derived from the Millstone Grit formation at Stanton Barn, in the parish of Melbourne, which is twelve miles distant from Long Eaton. The well is 60ft. deep, 11ft. in diameter, and at a depth of 50ft. adits or tunnels 5ft. high and 6ft. in width have been driven to collect the water. The south tunnel is 506ft. in length from the face of the well, and the north tunnel 1,104ft. From the north tunnel there are three branches to the northeast and one to the north-west, the total length of all the tunnels being 2,250ft. Besides the tunnel works, two large bore-holes were put down to the lower rock at a depth of 220ft., which yield a large quantity of water, and these are controlled by specially-designed valves, so that the lower water can be used or not, as may be desired. The capacity of the reservoir is half a million gallons, but land has been purchased for duplication when necessary. From the reservoir at Castle Donington the water gravitates to Long Eaton, a distance of nearly six miles, the main crossing the River Trent at Sawley Bridge. The principal industry at Long Eaton is the manufacture of lace, the factories being very large, and the town has in the past suffered severely from disastrous fires. The local board therefore laid great stress upon securing sufficient fire protection for their town. The mains have therefore been laid of exceptionally large size, and constantly charged at a pressure of 212ft. The general contractors for the works were Messrs. Price and Shardlow, of Nottingham, who have executed all the work for the Long Eaton local board and the authority of Castle Donington. Mr. G. F. Todd, of Derby, was the contractor for all the works executed at the expense of the Melbourne Authority. The engineer is Mr. George Hodson, M.Inst.C.E., F.G.S., of Westminster and Loughborough.

PURIFICATION OF LANCASHIRE RIVERS.—The work of improving the condition of the Irwell and the Mersey is slowly but surely progressing, and several authorities have recently moved in the matter. Last week the Mossley Town Council had the question under consideration; and the Rivers Pollution Prevention Committee submitted their report. It was decided to engage Mr. Theo. S. McCallum, C.E., of Manchester, to prepare a scheme for the interception and purification of the sewage of the town, with the view of obtaining the early sanction of the Local Government Board for the necessary borrowing powers.

The mission church built in Walworth, S.E., at the cost of the Pembroke College, Cambridge, Mission, will be consecrated on Oct. 1. Mr. L. S. Prior, M.A., an old Pembrokeian, is the architect of the church, which, like that of the Corpus Mission in Camberwell, has its club and classrooms in the basement.

Our Office Table.

THE Incorporated Association of Municipal and County Engineers will hold a meeting at Belfast on Friday and Saturday in next week, the 23rd and 24th inst. On the Friday the members will visit the Belfast Waterworks under the guidance of Mr. Robert Corry, the chairman of the waterworks committee. In the evening a conversazione will be held at the Queen's College. On the Saturday, after a council meeting, the members will meet at 10.30 a.m. in the City Hall, when the following papers will be read and discussed: "Progress of Municipal Affairs in Belfast," by Mr. J. C. Bretland, M.Inst.C.E., City surveyor; and "Londonderry, with some Notes on its Engineering and Sanitary Progress," by Mr. W. J. Robinson, A.M.Inst.C.E., city surveyor. In the afternoon there will be a visit to Queen's Bridge, Albert Bridge, and Main Drainage Works, and later on a reception at Ballymenoch House, County Down, by the Lord Mayor and Lady Dixon.

LAST year the Society of Architects, during their interesting and instructive tour in Belgium, visited Louvain, and went over the ateliers of Messrs. J. A. Poyers Bros., and were greatly pleased with much they saw there. The firm was by no means a new one, having been established in 1784 by the original Poyers, and some of the journeymen sculptors have worked in the same employ upwards of 45 years. Our readers generally, and those who formed the party in question more particularly, will therefore learn with surprise and no little regret that the firm is now broken up, and the many works of art the studios contained—the collection of more than a century—are scattered far and wide. The sale began on the 30th of last month, when the models, &c., went to the hammer. The auction was renewed on Thursday of last week, at which the machinery—some of the most complete of its kind in the world—was disposed of. Last Tuesday was devoted to the sale of the timber, marbles, &c., and the day following the works of art, &c., were sold. There were, in all, nearly 2,000 lots.

CONSIDERABLE correspondence is appearing in the Glasgow papers on account of a report from a committee of the town council, who state that the joisting of the new municipal buildings, built two years ago from Mr. William Young's designs, is infected with dry rot, which it is said will cost over £4,000 to remove. A correspondent of the *Glasgow Herald* asserts that the rot can be cured for £20, if the deafening be removed and a few holes knocked through the walls to give ventilation. The correspondent has the courage of his opinions, for he offers to give the £20 to the local infirmary if he does not succeed in checking the progress of the evil for the sum named.

THE new scale of fees charged for advertisement hoardings by the City Commissioners of Sewers is complained of as too high, while the regulations are alleged to be unnecessarily stringent. Fourpence per foot superficial is demanded for the first six months, and 6d. per foot afterwards in first-class streets and the return frontages thereto, and 2d. per foot superficial per month for the first six months and 3d. afterwards in all other streets. These rates, with the announcement that the charge for all hoards will be calculated on the assumption that they are to be 40ft. high, are said to make the advertising practically prohibitory, and on Tuesday, the City Commissioners of Sewers received an influential deputation of architects, builders, contractors, advertising contractors, and others, who presented a numerous signed memorial asking for a modification of the terms. The deputation claimed that there were benefits accruing to the public by hoards being licensed for advertising purposes in the prevention of dust and dirt during the removal of buildings, and in the exhibition of bills and pictures of an unobjectionable character, while the disadvantages attending the refusal to license hoards except at prohibitory fees were many. A charge of 10s. per 100 superficial feet per month for principal streets, and 5s. for others, as in the Strand district, would, they submitted, sufficiently meet the justice of the case. The memorial was referred to the Streets Committee for consideration and report.

It is stated that the Jarrah wood block paving

laid down at Kensington wears well, and is very uniform in quality. Several thousand yards have been laid. The blocks are 4in. and are close-jointed, and the surveyor, Mr. Weaver, reports well of the paving. At Hammersmith the same paving in 5in. blocks, with joints of ½in. in cement grout, has been put down. The close joints are said to wear best. On Brixton and Streatham Hills the Jarrah wood block has been laid, and a very excellent and even surface is the result, though it is laid in connection with the tramcar lines.

THE Rugby Rural Sanitary Authority have recently passed a resolution to abolish the by-laws in force for six parishes in their district, thinking it preferable that there should be no by-laws at all than that only a portion of the parishes should be affected. On being applied to for their sanction, the Local Government Board saw no reason for the proposal, and asked for a report of the medical officer upon the subject. Dr. Wilson had submitted a report, to the effect that he was strongly of opinion that the resolution should not be approved, and instead of rescinding the by-laws, he recommended that they should be extended to the whole of the parishes in the union, so that the board could have control of the water supply and sanitary arrangements. At the meeting of the authority, Dr. Townsend and others contended that the by-laws retarded building operations in villages. The building restrictions required an 18in. wall where a 9in. wall would do, and a 9in. where a 4½in. would do; and there were other unnecessary requirements, the result of which was that a person could not build a labourer's cottage under about £160 or £180. No labourer could afford to pay 5 per cent. on that, and the result was people would not build houses. The clerk pointed out that, while the by-laws might discourage building, they also discouraged the perpetration of nuisances. It was decided to await the reply of the Local Government Board to Dr. Wilson's report.

THE syllabus of the lectures to be given in the engineering department of the City of London College, White-street, Moorfields, by Professor Henry Adams, M.S.A., &c., has just been published. The courses, which open in the first week in October, include classes in civil engineering (a new departure), technical drawing and building construction, mechanical engineering, calculation of strains, quantity, town, and land surveying, and engineering field work. Mr. Henry Adams's name alike as a professor in his college and as a writer of handbooks and lecturer on scientific subjects stands deservedly high, and his students have been very successful.

ACCORDING to Mr. Stringer, the British Consul at Chiangmai, Northern Siam, the teak trade on the Meinam is declining at an alarming rate. At Chainat, the Customs station for the upper part of the river, 60,000 logs of teak passed in 1880, 30,000 in 1890, and only 9,500 last year. This is due to deficient rainfall, and to the effect of the indiscriminate working. Teak saplings are cut down in large numbers, and the clause in the leases forbidding the felling of small trees is disregarded. The consequence is that in Chiangmai there is reason to fear that in five years the only teak left will be that which is too far from the water to be profitably worked, and in Lakhon the foresters complain that all the best trees have already been felled.

The parish church of Hipswell, near Richmond, Yorks, was reopened on Wednesday, after restoration at a cost of over £1,200.

The Ruskin Museum at Meersbrook Park, near Sheffield, which has been closed for three months whilst undergoing internal improvement at a cost of £600, has been reopened to the public. New glass roofs have been placed over the picture galleries and the mineral room, and the buildings ventilated. The collection of Turner's pictures, which represent the artist's work throughout his life, are now on view at Meersbrook, having been lent from the National Gallery until November. While the museum has been closed, the curator, Mr. White, has visited Italy, and gone over what to art students is known as "Ruskin's ground." He went to about a dozen of the chief towns and cities, and on behalf of St. George's Guild collected from 200 to 300 photographs of pictures and of architecture, about which Mr. Ruskin has written very fully, or of which there are studies on the walls of the museum. The photographs will be mounted, and will be available to the public under the ordinary conditions of the use of the library.

The Architectural Association.—The offices of the Association will be reopened on September 26.

ERNEST S. GALE } Hon. Secs.

CHIPS.

Extensive additions are being made to Whittington Heath Barracks, Lichfield, for the War Office. The work has been intrusted to Mr. John Gethin, of Shrewsbury, for the sum of £18,732 10s.

The Dean and Chapter of Ely have received promises of nearly £5,000 towards the sum necessary for the repair of the cathedral.

About forty members of the Glasgow Archaeological Society visited Peebles on Tuesday, and proceeded to Neidpath Castle, which was described by Professor Veitch. The party then drove to Traquair House, a description of which was given by Mr. Duncan, the secretary of the society.

Plans of school buildings for the parish of St. James, Moss Side, have been prepared by Mr. J. Lowe, architect, Manchester. Accommodation will be provided for over 600 day-scholars.

On Monday the Swindon and district highway board appointed a surveyor in the room of Mr. C. Cole, who has resigned. There were 28 candidates, and Mr. Green, of Oundle, was elected.

There has just been cast at Munich the equestrian statue of the Emperor William I. destined for the conquered city of Metz. It will be inaugurated there with great pomp by the young Kaiser on Tuesday next, the 13th inst. The bronze has been executed by Professor Ferdinand von Müller.

During the past week some Anglo-Saxon graves in Watt's-avenue, Rochester, have been opened under the direction of Mr. George Payne, F.S.A., the secretary to the Kent Archaeological Society. The finds include an iron spearhead, several knives, a cinerary urn, and some opaque glass beads.

At the annual distribution of prizes in connection with the Manchester School Board science and art classes on Friday, it was stated that out of 29 of the most valuable prizes of the year offered to all the schools in the United Kingdom eight had been taken by Manchester.

A new vicarage is being built at Stoke, near Coventry. The contract has been taken at £2,510 by Mr. Thomas Collins, of Tewkesbury.

The Stafford Town Council have raised the salary of Mr. Bell, the gasworks manager, from £400 to £500 a year.

The Board of Trade proposes compiling statistics for the Blue Book relating to 350 of the largest building firms, master plasterers, master painters, &c., of the United Kingdom.

The new railway from Jaffa to Jerusalem is completed, and the first locomotive arrived at Jerusalem on Tuesday.

The works committee of the Dundee Gas Commission accepted on Monday offers for the erection of the new offices for the commission in Commercial-street. The total contracts amount to £6,700.

A stained-glass window, representing "Christ's Sermon on the Mount," has just been erected in the City Temple, to the memory of the late Matthew Mowson Proctor. It is from the studio of Mr. Thomas Grew.

The grammar school, Henley-on-Thames, is being warmed and ventilated by means of Shorland's patent Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

A credence table of polished marbles and stone has been placed in the Mission Church at Milborne Wick as a memorial. It is Early English in style, and has been executed from the designs of Mr. Henry Hall, F.R.I.B.A., of London, by Messrs. Harry Hems and Sons, of Exeter.

The work of restoration at St. Mary's Church, Uttoxeter, carried out in sections from plans by Mr. Charles Lynam, of Stoke-on-Trent, has just been completed by the opening-out of the west entrance. Messrs. Ward and Sons, of Uttoxeter, were the builders. At the same time the west window has been filled with stained glass by Messrs. Ward and Hughes, of London.

An order has been made for the discharge from bankruptcy of James Greenwood (trading as James Greenwood and Son), Sutton, Maltby-street, Bermondsey, S.E., and Cannon-street, City, builder and contractor—discharge granted.

An obelisk of red granite, 7½ft. high, with a pedestal of black porphyry, said to surpass in beauty both Cleopatra's Needle and the column on the Place de la Concorde, is shortly to be brought to Austria from Alexandria, where it has been lying in the Garden of the Austrian Consulate since 1847. It is to be erected at Trieste, to which town it was long ago bequeathed by the late Austrian Consul, Herr Laurin.

Trade News.

WAGES MOVEMENTS.

LONDON BUILDING TRADES FEDERATION.—A meeting of working men, under the auspices of their federation, was held on the Fair-field, Kingston-on-Thames, on Sunday morning, for the purpose of appealing to "all workers in the building trade to join hands and be ready for the all-important change to take place on November 1st." There was a very large attendance, over whom Mr. J. Nunn (Operative Bricklayers) presided. The speakers included Mr. Joseph Verdon (secretary London Building Trades Federation), Mr. H. Barnes (Amalgamated Society of Carpenters and Joiners), Mr. J. Rogers (secretary Battersea branch Amalgamated Society of House Decorators and Painters), Mr. Herring (Operative Bricklayers), and Alderman Taylor, L.C.C.

BELFAST.—The long continued strike in the building trade in Belfast was settled on Saturday afternoon on the basis of the employers agreeing to give 7½d. an hour, on the understanding that the question is not to be again raised till 1894. The men demanded 8d. per hour. In the compromise effected the plasterers are not affected.

BROMLEY, KENT.—After a strike which had lasted over five weeks, the bricklayers in Bromley returned to work on Monday, having obtained their request for ½d. per hour extra, in accordance with the new code of working rules agreed to at the last Building Trade Conference for the regulation of hours and wages in the whole of the suburban district.

CARDIFF.—A resolution has been passed by the London Building Trades Committee expressing sympathy with the Cardiff bricklayers, masons, plasterers, and plumbers who have been on strike for 18 weeks, and recommending their case to the favourable consideration of the various trades.

The War Office have determined to spend £16,000 on the erection of additional buildings on the north side of Hounslow Barracks, including two blocks of married quarters, each to accommodate 16 families. The first contract, for £8,000, has already been sealed, and the work is to be put in hand at once, under the direct supervision of the Royal Engineer Department.

At a meeting of the Governors of University College, Dundee, held on Monday, it was agreed to confirm the resolutions of a previous meeting in reference to the extension of the college buildings. These provide for the alteration and extension of the east block of the college buildings and for the improvement of the front elevation at a cost not to exceed £5,000.

An iron highway bridge at Gala, N.B., replacing a wooden one carried away by a flood, was opened on Friday. The bridge is over 100ft. in length and 26ft. wide. It rests upon abutments at each end and three piers—all being built of brick and sandstone masonry. The normal waterway of the river is spanned by iron girders, with lattice screen sides 4½ft. 10in. long. These girders forming a single span rest upon two principal piers. The remainder of the roadway at either end is carried on steel beams.

Major-General H. D. Crozier held a Local Government Board inquiry at Hanley on Tuesday into the application of the town council for sanction to borrow £16,000 for the purpose of laying out public walks and pleasure grounds, £2,000 for sewerage works, and £800 for street improvements. Evidence was given to the effect that the money was required for the laying out of nine acres situate at Northwood as a public pleasure ground for the East Ward, and of eleven acres, situate at Etruria, as a similar provision for the North Ward. There was considerable opposition raised against the site of the Northwood Park.

A statue to the Very Rev. Dean Bickersteth, D.D., to whose exertions the restoration of the west front of Lichfield Cathedral was due, has been added this week to the figures that adorn the west front of that cathedral. At the time the other figures were placed in position, one of the rural deans obtained subscriptions to provide a figure of Dr. Bickersteth, and the order was placed with Mr. Ingram, a London sculptor, who has carried out his commission. The figure arrived in Lichfield, but was not fixed, the chapter having previously resolved not to allow the figures of any living person, the Queen excepted. Now that Dean Bickersteth is about to vacate his appointment and leave Lichfield, the chapter have allowed the figure to be placed in its proper position. A vacant niche was left on the north side of the north-west turret in the third row of figures. The statue has been erected by Mr. Bridgeman. Dr. Bickersteth is represented in a standing position, in full clerical attire, holding a Bible in his left hand.

THE ART OF INCONSPICUOUSNESS.

"WILL not this part of the elevation look very plain?" is the common question of a client. "I hope so," would be the appropriate reply of his architect, if, after sufficient study, he has adjusted, as he wished, the various elements of his design. The tiro and the amateur take it for granted that every square yard of a building should have something ornamental about it. The artist knows better. He understands the value of contrast. His music is not all *fortissimo*; his picture is not all in high light; his elevations are not all covered with mouldings and tracery and carving. His triumph lies in getting the greatest effect with the least apparent effort, and to accomplish this the subordinate parts of his work must be quiet and subdued. "Put in plenty of plain wall" was a favourite maxim of the late Mr. Burges. It is a very safe one; but the difficulty lies in following it. A church, indeed, can easily be designed with great unbroken surfaces, but not so easily a house. More air, more light, are the things which sanitary authorities are always demanding, especially in our towns, and they are things which it is difficult to obtain if we keep as much blank wall as would artistically be best.

The architect lives in a world where beauty and use are always at war. It is his work to reconcile them. Even the insides and outsides of his buildings are commonly at variance, so that whatever suits the first spoils the second. Nothing ever comes right for him, everything has to be made right by care and thought and happy inspirations. As an artist he would like his walls to be solid and unbroken below, light and full of aperture above. As a practical planner he has to make them just the reverse. He finds the basement and the ground floor greatly in want of light—at least in town buildings. Higher up fewer windows and smaller ones are needed, and possibly the top story, being lighted from above, needs none at all. Architecturally, this is an upside-down arrangement; practically, it is often an inevitable one. What is the designer to do?

One thing he could do is to accept the necessity, to emphasise the sort of design it naturally points to, and to treat its details in an artistic spirit. If he cannot get the arrangement he likes, he may try to like the arrangement he gets, and to make other people like it too. This is what the builders of the Ducal Palace of Venice attempted with some success. The lower part, as every architect knows, is nothing but a great traceried arcade, without so much as a buttress or a pilaster. So open is it, that, for want of abutment, its arches would not stand an hour except for the tie-bars which hold them in. It is the very extreme of lightness, not disguised, but even made more prominent by the artifices of ornamental art. Over this comes a great flat, unbroken, almost unpierced wall, and then the low-pitched roof. The wall is covered with a kind of gigantic diaper pattern in marble slabs, and the windows are, or were, divided by light arcade shafts. But beyond all question, the plain and subdued part of the elevation is the upper half; while the enriched and emphasised part is unmistakably the lower one. According to ordinary notions, it is a topsy-turvy design. It is rich where we should have made it plain, and plain where we should have made it rich.

Yet it is highly attractive; and the attraction is not wholly owing to the beauty of its detail. The contrast between its arcaded stage and its unrelieved wall is most effective, although, for perfect success, their positions should have been reversed. It is a lovely picture, even if it is a picture hung the wrong way up.

In Mr. Street's book on Spain there is a striking sketch of the exactly opposite arrangement. A plain, solid wall of squared masonry rises to a great height with hardly any break or relief; then, planted on it, and slightly overhanging, is a story of the richest and most elaborate Gothic. Here we get the same sort of contrast as at the Ducal Palace, with the satisfactory feeling in addition that the contrasting halves are rightly placed. The inconspicuous piece of the design here is the lower one; and so, if it could be managed, we should usually wish it to be. The Spaniards were fond of these contrasts, and have left us Renaissance examples of them as well as Gothic ones. They used them, too, in the interiors as well as the exteriors of their public buildings. In the castle of Saragossa, for instance, there is an interior with walls quite plain for most of their height; then suddenly comes a deep, projecting cornice of extreme richness. This carries a beautifully light-traceried arcade or screen, with a smaller but much-decorated cornice above it, while the whole is crowned by a very effective wooden-coffered ceiling. The climate of Spain, with its brilliant sunshine, lent itself easily to such effects as these. There was no difficulty there in getting plenty of plain surface, because the windows could be few and small. But, how are we to get it in England? How are we to manage the art of inconspicuousness? It is one of our most pressing questions, and one of our most puzzling ones. Yet, for fifty people who write and speak on the way of decorating things, hardly one writes or speaks on the way of subduing them. We all know how to make features prominent; or, if we do not, innumerable persons are ready to tell us. But who has yet told us much about the way to keep features in the background?

The windows that come where the architects do not want them are not the only things he would be glad to hide. Doorways at times are equally obtrusive. Public buildings in modern times need an abundance of exits; and it may happen that these cut up the base of an elevation even more than the windows do. Here, again, the two opposite ways of dealing with such difficulties present themselves. We may make the doorways as beautiful and as rich as possible; we may allow them in this way to be their own justification; and we may let the design, as a whole, take its chance. This is what the Mediæval architects of France did in the case of such magnificent portals as those of Rheims and Amiens, and Chartres. Taken by themselves, they are the grandest things of the kind which the world has seen; taken as part of the general design, they are a mistake. We shall not use them as a precedent, if it is the building as a whole that we are thinking of. We shall be more inclined, by one means or another, to keep the doorways inconspicuous, so that the elevation may grow richer as it rises, and so that the eye may be attracted to its summit rather than its base. This was very cleverly managed—some people might say too cleverly—in a design for Victoria Cathedral, which we illustrated about three months ago. Here, in the drawings marked "New and Old," the western doorways were set back under a wide, low, segmental arch, so as to be almost lost to sight. Possibly inconspicuousness in this case went rather too far, but there is no doubt about the value it gave to the elaborate detail above.

Chimneys, like doors and windows, very often come where they are least wished for. They are not quite so obstinate, however, in

their demands, and generally offer a choice of positions. But in certain classes of work, custom and association demand that no chimneys should appear. For a climate like this the demand is absurd. Yet it must be owned that chimneys do not look well in pure Classic buildings, and that the more inconspicuous they are in such cases the better. Naturally, it will not do to keep them down too much. Practical necessities must be remembered, or the chimney which has been unduly humbled will revenge itself by sending up a crop of metal zigzags and corkscrews. It does not seem to be thought proper that a church should have a chimney. A poor, spiritless structure of the kind does sometimes rise up from the vestry roof; but it has the air of asking pardon from all the world for its existence. It tries to be inconspicuous, and is not—which is one of the worst faults that an architectural detail can commit.

Science is constantly sending us new problems to deal with: and it is a question in each case whether the solution is to be of the conspicuous or the inconspicuous class. Unfortunately, there is a tendency to leave the question unanswered. Ventilating pipes, for instance, have to be taken up from the drains. They cannot be beautified, but they might be concealed. Commonly, however, they are simply exhibited in their native ugliness, an offence both to the eye and the imagination, even in designs which aim at being artistic. The same may be said about sanitary work in general. A small part of it might be made presentable: the greater part of it might be made inconspicuous; but too often it is neither the one nor the other. We need not give more examples. The realm of the inconspicuous runs through the whole of art. Everywhere there is something to be kept in the background that there may be more force in the foreground, or some discordant necessity to be kept in decent obscurity. There is no art without contrast; and contrast needs the inconspicuous on one hand just as much as it needs the impressive on the other. It is the last that gets all the praise, but it may be the first that has taken most of the skill.

BAD HOUSE-DRAINAGE.

DURING a time of threatening epidemics it is very necessary for sanitary authorities to use all the safeguards they can to prevent the flooding of houses in low-lying districts, which are numerous in the Metropolis. Only lately the Battersea Vestry have had brought to their notice the recent inundation of some 500 houses during the very heavy fall of rain in August last, and the existence of many hundreds of houses the basements of which are below the level of the drains, or are so badly provided that when a storm takes place the basement floors are flooded. Other localities at Clapham, Fulham, Putney, Kennington are equally subjected to the inconveniences arising from building below a safe level, or so close to it as to impede the free discharge of storm-waters. Yet, although these localities yearly suffer from floods, houses continue to be built on land frequently saturated with water, the drains introduced being merely subterfuges which only carry away the surface-water in dry weather. In several new estates we find cellars excavated which are full of soakage water. When it has partly percolated the surrounding soil or evaporated, the walls are carried up, the house is covered in and let, and the inmates are none the wiser that their fires are really drawing into the house vapours of the most obnoxious kind. The drains put in merely lower the water-level to a few inches below the basement during dry weather; but immediately a heavy rainfall occurs, the basement is found to

be again under water. At Battersea, for example, it is well known there are hundreds of houses which have their basement floors level with and below the invert of local sewers. How can those houses ever remain free from floods? Mr. John Burns, M.P., in a letter to the Battersea Vestry, reminds them of this condition of things, and that many of the connections between houses and local sewers are very imperfect; the pipe sewers are too small, and should be made into brick sewers. Many of the brick sewers are equally inadequate, and can only be cleansed by the chain and rod process. The desirability of enlarging the connecting and local drains we have lately advocated as one of the means for remedying the frequent surcharge of flood-water and preventing the "back-watering" of houses having insufficient fall to the sewers. Mr. Burns, in his letter, says, "I think further that the practice of having a chamber 10 or 14 ft. from the main sewer, with flap on inlet to chamber is not as good as continuing the local sewer into the main one, with flap on point of junction with it. Altogether, there is insufficient pond room, and also insufficient access to pumping station and main sewer by the local drains. This is proved by the fact that the recent rain-storm commenced at 5 a.m.; at 5.15 floods took place in Ingrave-street, whilst at the pumping station there was not enough water with which to commence pumping until 6 a.m. From investigation, I find that many of the houses were flooded before it was necessary or possible to start the pumps through lack of water in the "sump"—i.e., at 6 o'clock, and when the main sewer at the pumping station was full at 8.30, the water had subsided from local floodings. This is also confirmed by the fact that floods have occurred when there has been no need to pump, and with a sewer only half-full. This means that either choking takes place, or that local connecting sewers with the main sewer of York-road are inadequate." If these facts are as stated, it is clear evidence that the fault lies in the connecting drains between the houses and main sewers; it proves, in short, that the connections are either much too small or are laid too level, or are choked and do not discharge their contents. The whole of the levels require readjustment. We have no satisfactory proof that this state of things does not exist in other parts of London subject to floods. The local pipe sewer is no longer capable of carrying away the flood in many instances, or the intercepting chamber referred to by Mr. Burns is not low enough or becomes over-charged with surface-water before the main sewers are in operation or running full. The consequence of which is that the house-drains become speedily overcharged, and as they cannot discharge at the sewer end fast enough, their contents are driven backward into the houses. Again, when it is stated that many houses are flooded before it is possible to start the pumps, we may be sure the "sumps" or wells at the pumping stations are not properly connected with the local drains, or their level must be above that of the basements. We should be inclined to think the former is the case. Under the present system of sanitary inspection it would seem preposterous to entertain the opinion that house-drains are often mere disguises, and are never properly connected with the sewers; but these statements appear to confirm the suspicion, because if hundreds of houses are flooded before the sewers are running full, it proves something radically wrong with the connection.

Other grievances have been reported equally prejudicial to the health of districts, such as the "percolation of land water into bakehouses, public-house cellars, and basements." Mr. Burns mentions the fact that several public-houses and bakehouses were

subjected to the percolation of clean water through the walls of their cellars, which was of frequent occurrence. Much of the water comes up through gullies contaminated with sewage, as in the case of a bakehouse. Of course, the mischief may arise from the same cause—viz., the want of capacity or discharge of the drains to carry away the storm or land water; but in some instances the back yards and areas are without any means of drainage, there being no gully-gratings. The water not finding escape, enters the sunken areas round the house, and percolates through the walls into the basements, or saturates the spaces beneath ground-floor rooms, much to the detriment of health. We have before urged the necessity of a rule or by-law to compel owners to construct concrete or asphalt basements, and Mr. Burns suggests that owners of basements lower than they should be ought to be made to abandon them or concrete them. The whole question of the re-drainage of our large and rapidly increasing districts is one that must before long be considered. Vestries are locally responsible, but the London County Council must take the initiative step in reconstructing the present system, which is already inadequate to meet the growth of large building areas.

WORKING DRAWINGS AND SPECIFICATIONS.

NOTHING is more troublesome, not to say repulsive, to the young artistic aspirant whose prospect of professional achievement looks fair and easy than to have to descend from the cloudland of the imagination to the office labour of making a working drawing or writing a specification. The thing is essentially repugnant to him. From fancy to fact the descent is not at any time easy or agreeable. To sketch an impression on paper, say of some stone detail or a piece of woodwork, may be bewitchingly alluring; but to come to analyse one's thoughts and reduce them to a matter of stone-cutting and joggles and cramps, or of framing and jointing, is to allow all the poetry and charm to evaporate in the process. The enchantment is gone—the spell broken. Just imagine for a moment a poet or a painter taking to pieces his composition, or an architect who had designed a beautiful *flèche* having to sit down and see how such a structure can be erected of timber and iron and lead, to calculate its weight, and to consider it as a skeleton of timber or iron. The mind which had conceived the thought or image in its abstract beauty of completeness coolly and deliberately looking upon it from a logician's or a mechanic's point of view! We might as well expect a painter of landscape to explain how the yonder ruin or cottage in his composition was planned, or for him to give us the working perspective lines or the anatomy of his figures. As reasonably we might ask the poet to prove the grammatical correctness of his verse. Critical accuracy is not looked for in artistic creations. The analytical process is, notwithstanding, necessary to the architect according to our modern notions of his duties, though, as M. Cesar Daly says, the poetical side of architecture is too neglected. The public do not think so, and often with a will that shocks the high-art notions of some, when they call upon the architect to become an expert sanitary engineer, to know all about drains and hot-water apparatus, and to do sundry things that are more in the way of the plumber and bricklayer.

To take, for example, working drawings. These imply a variety of technical requirements that can only be learned in the workshop or on the building. Is it not a fact that a large proportion of such details are

undertaken by the clerk of works in large works, and that these are passed by the architect? We are quite ready to admit that an able clerk of works, with the measurements and materials, and actual requirements at his fingers' ends, is more able to make a practicable detail drawing for the mason, or bricklayer, or carpenter, than the architect who may be miles away from the building, and ignorant of the actual conditions; and we are prepared to say the practice is more in accord with the ancient traditions of architecture than the modern one of some assistant preparing a working drawing from the small-scale contract drawings under the general directions of his employer. We know from experience what the assistant often turns out from such crude data. If it is the working detail of a brick arch or window, it is seriously defective. The "bond" has not been observed, the courses have been set out wrongly, the moulded part of jamb or arch cannot be worked with the moulded bricks on the building, or the dimensions may be found to be altogether "out." It cannot be expected that an assistant or pupil to a busy architect has the practical knowledge to enable him to set out "bond," as, for example, the mullions of a bay window, or will take the trouble of obtaining exact dimensions from the actual work. The drawing is merely an enlargement of the $\frac{1}{4}$ in. scale drawings. Much less can he prepare "full-size" drawings of any such detail. But the clerk of works on the building can obtain the exact requirements of the bricklayer or mason. It may be said the architect ought to prepare his own details. Certainly he should, if possible; he visits the work in progress, and can see exactly the requirements; he knows what he wants, and can give his own instructions. But how many really can do this in large buildings?—and, we may add, are they all such practical men—masters of the trades they profess to direct? These are questions which are becoming more urgent. Competition and technical education have been disuniting the profession and the trade, making the gulf between them wider. The architect in full practice finds his hands full in making negotiations, attending clients and committees, competing for large buildings, without attending to details of works in progress, though we know, according to the old *régime*, he paid as much attention to the details of his building as he did in its design. Running after commissions and competing did not then enter into the duties of the architect.

The clerk of works has his own duties and obligations to discharge, and to require him to make working drawings would be to impose on him a labour in addition to his already onerous duties. Further than this, his responsibilities as local superintendent of the work would militate against such employment. He could not act with the same independence as he does when he has to enforce the execution of the architect's details if he had himself to prepare them. A suspicion of connivance between him and the contractor might arise. Yet, for all this, he is in the most advantageous position for knowing exactly what is wanted if the architect could imbue him with his artistic spirit. Of many of the constructive details he is master; the early training of a clerk of works, often having fulfilled the position of builders' foreman, or coming from the ranks of working joiners, masons, or bricklayers fits him for the duty; but then the unhappy estrangement between what is artistic and what is practical, makes it impossible that any architectural details should be intrusted to his hand. Hence the present arrangement of all drawings being prepared in the architect's office, though it may be urged that many of those are necessarily modified, altered, or redrawn by the clerk of works before they can be executed.

The working drawing has not yet been made a subject of study amongst the younger men of the profession, who have regarded it with the same aversion as they would in taking up an advanced course of mathematics. There is too much of the "smell" of the workshop about it: it means an acquaintance with materials, market sizes, thickness of stuff, and trade methods, which things are unpalatable to the tastes of artistic draughtsmen. The course of study begun at the Association may do something to encourage the study as a special branch, though we have no very strong belief that anything but personal interest in the technics of the profession will ever make an office-trained architect a skilful artist in wood or masonry or any other material. The technical school and workshop may instruct in the use of tools and manual processes, but will never make a designer of details—that implies power of seeing, or of conceiving, as well as technical knowledge of cutting stone, or moulding brick, jointing, &c. We find a clever joiner unable even to draw on paper what his work will look like—his mouldings are execrable, his profiles clumsy or commonplace—one reason why a clerk of works, brought up as a carpenter, makes a poor designer of details, and can very seldom turn out a decent drawing of any detail for a mason or bricklayer. The more general knowledge of the architect enables him to take a better proportioned view of the trades; his wider acquaintance with old examples and details, and his artistic knowledge are advantages which the operative has not—one reason why an architect's detail has more general feeling with the design than one prepared by a craftsman, though it is defective in technical knowledge. The two things can only be acquired by the architectural student drawing his details in the building or in the workshop.

Then we have the tiresome specification, which, if anything, is worse and more repulsive than the detail. Ordinary clauses we may suppose are understood by, and present little difficulty to, the architect; but specifications of new inventions and manufactures are a source of trouble, and are yearly becoming more irksome. The question generally is not so much what to specify, but how to specify. It will not do to place oneself unreservedly into the hands of some enterprising firm who may be thoroughly honest, and yet desirous of making a good bargain. An architect who simply goes to the manufacturer and tells him what he wants done, but does not make any reservations or any conditions, must not wonder if he finds himself in a rather awkward position sometimes, unable to compel compliance to his requirements. But the fact is that the manufacturer has the advantage. The architect knows nothing of the manufacture—it may be a patented system of flooring, or a new plaster or paint which has been found of value, and he is inclined to place himself unreservedly in the patentee's hands. Only the manufacturer can give the information or directions for its use or fixing, and therefore if a specification has to be written it can only be done by him. The architect writes for information, which being supplied, a clause is introduced into the specification that is very inadequate. The better way is, of course, to enter into an agreement with the manufacturer—a correspondence between the parties constituting sometimes a contract—binding the manufacturer to supply the materials and execute the labour necessary, the whole to be done to the satisfaction of the architect. Unfortunately, the latter has no guarantee that the work will be done to his satisfaction. Thus we may imagine that a certain depth of iron joist is specified, but which is found to be insufficient to make a rigid floor, or that two coats of a certain paint, the agreed

allowance, has been found not to produce the desired effect. An additional column or two may be required, or a third coat of paint, and of course in either case it is an "extra." The manufacturer has overrated his goods, or underrated the requirements of the architect—these things follow as a matter of course. It is a common thing to overstate the virtues of a new invention or material, and it is, therefore, all the more necessary that the architect should be on his guard in discovering, if he can, by independent evidence, or from others who have used the said invention or material, the actual advantages claimed for it. Specifications of all new things should, therefore, be prepared with some caution, and probably the best way to meet the difficulty in some instances is to allow the manufacturer to write a specification that shall cover all risks, binding himself to perform the work to the requirements of the architect or his employer.

IRON ARCHES OF LARGE SPAN.—I.

CAST IRON.

IF we compare the earlier examples of cast-iron arches with structures similar in principle of design and description of material belonging to a more modern date, we shall find that there does not exist between them that extreme discrepancy in relative proportions which characterises bridges of wrought iron under the same conditions. The first iron bridge erected in this country was over the river Severn, near to Coalbrook Dale, whence it derived its name. It was a cast-iron arched-rib structure, having a clear span of 100ft., and was constructed more than a century ago. The largest cast-iron arch in the world is still the centre arch of old Southwark Bridge, with a span of 240ft. Taking the span of Coalbrook Dale Bridge as the datum or starting point, it is evident that succeeding examples of cast-iron arches have surpassed their predecessors with respect to that dimension, in the proportion of $2\frac{1}{2}$ to 1 nearly.

In the case of wrought-iron bridges, the ratio between ancient—if we may use the term—and modern constructions, in regard to span, has a far wider limit. Assuming the initial span of the wrought-iron prototype to be the same as that of the cast iron, namely, 100ft., the latest and greatest triumph of bridge-building, in this or any other country, exceeds this modest dimension by about seventeen and a half to one. From this comparison bridges on the suspension principle may be fairly excluded, as, with one or two exceptions, they were very early constructed of spans which are considered "large" at the present day. It will thus be seen that whilst the cast-iron arch and wrought-iron suspension principles sprang, as it were, into nearly full maturity, the horizontal girder principle passed through a protracted, and sometimes perilous, period of infancy and growth. The reasons for this sudden development of these two particular types of bridge construction, are to be found:—First, in the fact that cast and wrought iron exert, individually, a powerful resistance against strains of a distinctly opposite nature. Secondly, although the knowledge of the capabilities of these two materials, and their ultimate behaviour under severe loads, were at that time but very imperfect, yet engineers had both the ability and judgment to utilise their respective constructive values to the best advantage. The proper form in which to design cast and wrought iron beams and girders was still undergoing the process of testing and experiment, and a correct result was not arrived at until the part played by the "inertia" of the section, with respect to its strength, was recognised as a most important feature in the calculation of its resistance.

We shall thus be prepared to find as we proceed with our subject that the form of the cross-sectional areas of the arch-ribs employed in the earlier examples of cast-iron arches do not comply in this particular with the dictates of mathematical theory. This will be pointed out when treating of the "moment of inertia" of differently shaped sections.

It must be admitted that cast-iron in the form of an arch-rib possesses many and strong claims upon the consideration of engineers, and these claims had additional weight at a time when its comparative weakness under a heavy live weight,

or impactive force, was not very well known, or, if known, frequently neglected or ignored. The metal itself was cheap, could be used *en bloc* without the necessity of accompanying angle, tee, channel, or other separate sections of iron, and the usual large amount of riveting which constitutes the inevitable adjunct of ordinary wrought-iron bridge and girder work. Again, its great resistance to strains of a compressive character, amounting as a maximum to 50 tons per square inch of sectional area, rendered it peculiarly well adapted to the arch type of bridge, since the strains upon an arch-rib are wholly of that description. Under these conditions no call is made upon the tensile strength of the same material, which amounts, per same unit of area, to barely one-sixth of its resistance to compression. The chief advantage of applying cast iron in the especial form under notice is that the resulting strains being of one description only permit of an equal or symmetrical distribution of material about the central axis of the rib, and this highly favourable condition obtains whether the rib is formed with upper and lower flanges, or without them. The ribs of the early specimens of cast-iron arches were without flanges, and resembled in form a deep plank set on edge; and it can be easily shown that in this instance the neutral axis passes through the centre of the cross section of the plank. A practical example will demonstrate this more satisfactorily. In Fig. 1 is shown a cross section of one of the ribs of the Chepstow Bridge over the river Wye. There are five cast-iron arches in the whole structure, the centre arch having a span of 112ft. There is a small top flange to the ribs; but as it is intended solely for bolting the ribs to the spandrel standards, and is, moreover, of very insignificant dimensions, it cannot be included in the sectional area of the rib for any purposes of calculation. In the rectangular section C D in Fig. 1, let b

FIG. 1.

equal the breadth, and dx the depth of any very thin layer, supposed to be parallel to the neutral axis A B, and situated at a distance from it represented by x . Then the area of this layer will be equal to $b dx$, and multiplying this quantity by the square of the distance from A B, we obtain for its moment of inertia, calling the latter term I, the expression $I = b x^2 dx$. Considering at present only one half of the rectangular section, or that part of the section above the line A B, it is clear that if successive layers of it were taken, and each layer multiplied by x^2 , the sum of all the layers so treated would be equal to the moment of inertia of the whole half-section. Expressing this summation or integration by the usual symbol, and putting I for the moment of inertia, we have for the plank

$$I = \int b x^2 dx.$$

Since the section is uniformly and symmetrically distributed about the line A B, and the moments about it are also equal, that line represents the neutral axis, and is at the centre of the cross-section. By similar reasoning, the moment of inertia of the lower half of the section will be equal to that of the upper, so that in this instance, if I equals this total amount, we have—

$$I = 2 \int_0^{\frac{d}{2}} b x^2 dx,$$

from which, by integrating—

$$I = \frac{2 b x^3}{3}.$$

Taking the limits of x between $\frac{d}{2}$, where d = the total depth of the section and $x = 0$ at the centre, we finally obtain—

$$I = \frac{b d^3}{12},$$

which is a general form of expression for both

solid rectangular sections and flanged girders, provided that in the latter the same conditions of the uniform distribution of the material is insured.

In the formula—

$$I = 2b \int x^2 dx,$$

when applied to sections in which the material is not uniformly distributed about the axis, the term b will vary with the distance x , and must be expressed accordingly. The expression of I for triangular and other unsymmetrically shaped sections will furnish examples of such substitutions. In all the equations and formulæ relating to the value of I , the importance of the factor d , or depth, of the section with respect to its resistance to strain, is apparent. If for bd^3 , the numerator of the fraction giving the equation for I , we write ad^3 , we obtain the result in terms of the area. If, again, we make d equal to unity, we obtain $I = \frac{b}{12}$. As already pointed out, the

value of b was hardly recognised in the earlier forms of arched-rib sections, any more than it was in the primitive examples of ordinary cast-iron beams; and it was not until both theory and experiment demonstrated its importance that its value became properly appreciated. It is evident, therefore, that it does not necessarily follow that any given value for d will produce the best section. On the contrary, a better form of section may be produced, when both the depth and area are constant, by a simple different distribution of the material with regard to the value of x . In some instances, moreover, the original dimension of d may be diminished with advantage.

In future practical illustrations we shall not consider any cast-iron arch with a less span than 150ft. as coming within the scope of our subject. In small examples of construction there is not that demand or regard for scientific design which becomes imperative when the work attains to a character of some magnitude.

livered on Thursday, remarked that sanitary engineering might be called a modern science, as it was only since the passing of the Towns Improvement Act of 1847, and the Public Health Act of 1848 that serious attention had been given to the subject. Investigations were then made into the causes of zymotic diseases in towns, and it was found that want of efficient sewerage, defective house drainage, pollution of drinking wells, badly-constructed dwellings, and want of ventilation were among the main causes of the high death-rate. The sanitary engineer might then be said to have been created. To-day England stood in the front rank, America being her only competitor of importance. He then discussed the principles to be kept in view as regards town sewerage, especially as to the rainfall and the gradient of the sewers. He maintained that the Metropolitan scale, which allowed for only $\frac{1}{4}$ in. of rainfall in 24 hours, had failed, and it would fail everywhere where it was adopted under similar conditions. In London special supplementary surface drainage outfalls had been constructed to remedy the defects that arose from the design of the metropolitan main sewerage, and in other towns where this scale had been followed the local authorities would have to adopt similar remedial measures. There were advantages attending the separation of the rainfall from the sewers; but if by a separate system a duplicate system of drains to every house was meant, that was not either practicable or desirable. Sea outfalls required the greatest care as to their situation and construction, and if the currents were not favourable, crude sewage should not be discharged from them. In cases of this kind precipitation must be resorted to, and the effluent only discharged into the sea. With regard to the ventilation of sewers, after 40 years' experience, he had come to the conclusion that an open sewer down the centre of a street, with a good fall, would be the best form of construction. That, however, was impracticable; and he therefore said, Get as near to it as you can. The system of precipitation of sewage had lately grown more into favour. This was due, first, to the improved means of disposing of the sludge; secondly, to the failure of the so-called sewage farms; and, thirdly, to the growing tendency to combine precipitation with land filtration. Fortunately for England, the local authorities were now better prepared to resist cholera than in 1866. But our towns were still overcrowded. Much had been done during the last year under the Housing of the Working Classes Act, 1890; but a danger still remained, which local authorities must face. What was wanted was the erection of suitable dwellings to take the place of those condemned. Here was a splendid opportunity for the architect—to design a good, healthy dwelling for the poorer working class at a reasonable cost, so that local authorities might be induced to erect them. A good model working-man's home was wanted in our crowded towns, where there should be a large dining-room and a reading-room common to all, with a separate bedroom for each lodger. The sanitary architect should insist upon the following points:—(1) A naturally dry subsoil, or one made so by land drainage; (2) a damp-proof course, either of asphalt or two thicknesses of slate in cement; (3) walls built of hard kiln-burnt bricks, which would keep out heavy rains, and in the south of England hollow walls; (4) a good pitch to the roof and outside gutters—eaves gutters if practicable; (5) good ventilations under the floors and to the rooms by separate ventilating flues next the smoke flues as exits, and proper inlets; (6) drainage in stone-ware pipes outside the house, disconnected with the main sewer, and ventilated, or under the house cast-iron pipes with lead joints; (7) water closets with wash-out or flush-out basins, with soil-pipes outside the house carried up to the full size and ventilated; (8) sinks of all kinds and baths to be disconnected with the sewers, and to discharge over open gratings.

Mr. W. Hepworth Collins, of Bolton, forwarded a paper on "The Pollution of Rivers and Canals by Manufacturing and Industrial Operations." The writer urged that there was no reason why every manufacturer should not be compelled to deal with the polluted water upon his own premises. Possibly the more effective and economical way of dealing with the enormous volume of pollution from manufacturing sources was by concentration and by evaporation followed by condensation. The section resolved that it was

desirable that local authorities should have enlarged powers to compel manufacturers to cleanse the rivers into which their waste products ran, and if they did not do so, to carry out the work and charge the manufacturers with the cost.

Other papers of interest read in this section were that by Mr. Hubert L. Terry on the "Smoke Nuisance," who called attention to the little-used special powers of section 91, sub-section 7 of the Public Health Act of 1875, and advocated the appointment of chemical engineers as smoke inspectors; Dr. H. Kentford's paper on "Drain and Soil-pipe Ventilation," and that by Mr. Henry Law on "Apparatus for Softening Water."

In another section, Dr. Sykes read a paper on burial reform, in which the author advocated a system of earth-to-earth burial, but without coffins, which, he said, were an innovation that crept in in the time of Charles I. He urged that the control of the cemeteries should be vested solely in the Local Government Board. Sir Charles Cameron, while condemning interment in crypts and vaults, said he failed to see where harm could arise from well-kept cemeteries. Sir Thomas Crawford, while in favour of cremation, also saw no danger in a properly-kept cemetery that was not overcrowded. Other speakers advocated cremation.

CONSTRUCTIONAL DRAWINGS.—VI.

A ROOF IN STEEL.

THE strain in the diagonal tie-rods will vary according to the direction of the wind: those inclining to the left being strained when the wind is coming from the right, and those inclining to the right when the wind is coming from the left. The vertical strut NN' will be strained in either case.

The difficulty which is experienced in drawing a diagram for this form of roof on arriving at the strut EF, where the force is resolved into three directions, may be overcome in the following manner: Assume that the equal loads 2, 3, and 4, 5 cause equal stresses in the tie-rods DE and FG, and therefore that Dx drawn parallel to GF cuts off Ex equal to resultant of tensions

DE and FG acting in EF. To this add component of load 3, 4, as found at 4, z, which equals total stress in EF.

For specification for steel-work see BUILDING NEWS, Aug. 26, 1892.

I am indebted to Mr. D. C. Rattray, C.E., of Manchester, for the general design of this roof. The joints have been largely modelled upon those of existing examples of recent construction.

THE LIBRARY OF MESSRS. MASON AND RICE, ARCHITECTS, DETROIT.

THIS sketch shows the fireplace and a portion of the fittings of the apartment. A library is often now considered to be an indispensable adjunct to the offices of the larger firms of architects in America. Indeed, one is advisable anywhere where a collection of architectural works and illustrations is made. In such an apartment they can be kept in dust-tight cases, and suitably arranged for handy reference. And what more fitting than that architects should give a distinctive character to the room by the taste and appropriateness of its decoration, and by careful selection of good furniture and works of art? Our sketch was made from a photograph kindly sent by the architects.

Messrs. Watt and Wilson, of Glasgow, have nearly completed their contract for the section of the aqueduct from Lake Thirlmere to Manchester, between Barnfold, Goosnargh, and Chorley, about 19 miles, for £135,000. On this length there have been erected eight valve houses.

One of the small hill-side crosses occasionally found in the Lowlands has just been unearthed at Anworth, Dumfriesshire, and has been set up within the ruins of Ruthven's Kirk. It is a slab of red sandstone, and is at present 48 in. in length, 14 in. across its widest part, and about 4 in. thick. The cross, which is now 26 in. in length, and rudely incised, has its upper arm broken off. The width across the arms is 11 in., and the usual small incised boss appears in the centre. Proof was also found of the existence of a Pre-Reformation Church in a number of coffin-shaped tombstones roughly fashioned and shaped.

W. H. B. 1892

THEATRES.—VIII.

By ERNEST A. E. WOODROW, A.R.I.B.A.

WE have already seen that the placing of the seats in the auditorium (Chapter VI.) is a matter of importance in reference to sighting and acoustics; now we have to consider their arrangement with respect to ingress and egress. In London the architect must be governed by the seventeenth regulation of the London County Council, which declares that a clear passage or gangway not less than 3ft. wide shall be formed at the sides and in the rear of the seating in every part of a theatre; and that such passages or gangways shall at all times be kept entirely free from chairs, flap-seats, or other obstructions, whether permanent or temporary. By this it will be seen that a fixed width of gangway is required, irrespective of the length of the rows of seats, and irrespective of the numbers likely to use the gangway as an exit. Authorities do not seem to agree upon this point. It is said by one that the number of seats in a row should never exceed twelve without an intervening gangway, and that the minimum width of the gangways should be equal to two seats in the respective section of the auditorium; these figures are given as the width of gangways in the various parts: stalls, 4ft.; pit, 3ft.; dress-circle, 3ft. 4in.; upper circle, 3ft.; gallery, 2ft. 4in.; the last named of which with a double gangway having dividing handrails firmly secured to the guard rails round the circle front.

I cannot quite agree, considering the question from the exit point of view, that the pit and gallery need a less width of gangway than other parts. The width of the gangway should be governed by the number of persons using it, and it should widen towards the exit, as each additional row of seats discharges a fresh current of people into it. This principle appears to have been adopted in New York, for in that city the regulations say that no seat in the auditorium of a theatre in New York can have more than six seats intervening between it and an aisle—that is to say, there cannot be more than thirteen seats in a row—and, further, that all gangways must be at least 22in. for every 100 persons, no aisle shall be less than 3ft. at its narrowest part, increasing at the rate of 1in. for every 5 running feet towards the exit.

Centre gangways have been objected to by managers, as they assert people will stand in them, obscuring the stage from those behind, and creating a disturbance which may produce panic. In a well-governed theatre surely the management can cope with such a small difficulty and insist upon the people sitting down and leaving the gangways free. Centre gangways have been objected to on another score, as it is said the actors object to the empty space in front of them, as it affects their performance. Upon that point I cannot comment here.

There is so much divergency of opinion in the question of seating and gangways at home and abroad that I propose reviewing shortly the requirements in Continental cities.

Very strict rules exist in Austria; the stall seats there must be hinged, to lift up, having a depth of at least 1ft. 9 $\frac{1}{2}$ in., a width of 2ft. 3 $\frac{1}{2}$ in., and a clear space in front of 1ft. 3 $\frac{1}{2}$ in. The minimum size for numbered seats is 1ft. 7 $\frac{1}{2}$ in. by 2ft. 1 $\frac{1}{2}$ in., or rather less than required by the London County Council. When seats in the pit and the galleries of the Austrian theatres are approached from either side, the space between the rows must be 4ft. 1in.; if only from one side, then the rows may be 3ft. 3in. apart. Cross gangways must divide every six seats, and the exit doors must be in line with them. Where, however, this is impossible, a clear space of at least 5ft. must be left all around between the last row and the wall.

In the evidence given before the Select Committee of the House of Commons this year it was shown by some witnesses that it was desirable in their opinion to license a theatre to hold only a certain number, like an omnibus or steamboat. In Austria such provision is made, and theatres are licensed to hold a fixed number of persons, and such number, whether in boxes, stalls, numbered or unnumbered seats, and the spaces set aside for the special purpose of standing-room in pit or gallery, may not be increased on any pretence.

The obstruction of gangways by standing, is certainly most objectionable, although it has been argued that those standing will be the first to be out of the building on an alarm being

raised; true, but they must impede those behind them to some extent. Standing room in spaces set apart for the purpose, as allowed in Austria, does not appear objectionable, provided it is done only to a limited extent, and does not block the line of exit.

The use of camp-stools in gangways everyone would surely forbid, as also the closing of gangways with flap or automatic seats; but in Brussels there is this rule: "No stool may be placed in any gangway without the consent of the local authority; these stools should be of a pattern to be approved, and should fold back in such a manner as not to interfere with the passage-way." But it appears it is self-evident that the time occupied by the person seated in rising and walking out of the gangway is valuable time lost, and should one occupant of such a seat fail to rise, through fright, or should the spring or automatic seat not act, the gangway would be effectually blocked and rendered useless. Gangways cannot, in my opinion, be too clear or too numerous.

There is another rule in Brussels which, one might almost say, contradicts the one already quoted—the chairs and seats, with the exception of those in the private boxes, should be fixed to the floor. There must be at least two lateral gangways, and a third one may be required by the authorities; in this city, as in the regulations of Austria already cited, the width of the gangways is made in proportion to the number of people who have to use them, being calculated upon a basis of 3ft. 3in. for every hundred persons.

The number of seats in a row without intersecting gangways is limited in St. Petersburg to twelve; a middle gangway must be 4ft. 5in. wide, and two side passages 2ft. 11in. wide.

Paris seems to be behindhand in her requirements on this point, as all seats upon the ground floor of the auditorium, and those of the galleries must be provided with only two side gangways not less than 3ft. 3 $\frac{1}{2}$ in., which, however, may be substituted by a single middle passage 4ft. 3 $\frac{1}{2}$ in. wide—a provision which, in my opinion, is totally inadequate for these two large divisions of a theatre.

From these rules it may be taken that from twelve to thirteen seats in a row is the maximum that should be allowed without an intersecting gangway, and that the gangways should widen towards the exit. All chairs and seats should be securely fixed to the floor, as a loose chair will fall over and trip up anyone hurrying out of the building. The pattern of chair to be used is important. In Paris there is a rule that the seats of the chairs must fold against the backs. I drew attention some little time back to an automatic tip-up chair of German invention; this was illustrated in the BUILDING NEWS March 25, 1892. The object of this chair was to allow gangways from back to front, as well as from right to left. Seats made after the manner of American bent-wood chairs have been recommended as comfortable and cool in summer; stuffed seats are liable to harbour dust, and be too warm for comfort. For the personal convenience of the audience, each seat should have a division made by means of arm-rests, for where the seats are so divided the manager cannot "pack" the house to the inconvenience and danger of the public. This would be a simple manner of limiting the number the house should contain, at any one time, and be a means of fulfilling the recommendation made before the Select Committee to restrict the number of persons to be accommodated in a theatre, &c. The numbering and "booking" of every seat in the auditorium, as adopted at Olympia when under the management of the late Mr. Barnum, and as now carried on by the managers of this place of entertainment, certainly has met with the approval of the public, as it permits all classes to visit the entertainment with equal comfort. I cannot say whether the theatre managers would agree to "book" the cheaper parts of the house in the same manner; were it done, it would be a cure for overcrowding, and secure admission to the theatre without the waiting at the pit and gallery door for hours before the commencement of the performance. On this subject there will be more to learn when considering the entrances and exits to a theatre. The managers' objections to booking the cheaper seats are doubtless the inability to admit any above a fixed number during the run of a successful piece. The casual passer-by would not

have the same chance, as now, to obtain a good seat in the house, and people who had only made up their minds, on the spur of the moment, to visit the theatre would be deterred from doing so, through not having previously booked their seats.

Lately an improvement has been made in providing in the circles doors or openings at the end of every or every few rows of seats leading directly into the corridors. There is only one objection to this arrangement: that where the doors open into the side corridor, they are apt to become obstructions to the crowds passing along the corridor. The St. Petersburg regulations insist that to each intersecting passage there must be, on the ground floor, a corresponding separate exit into the corridor which surrounds the auditorium, and for every 150 visitors there must be one exit not less than 4ft. 8in. in width. In the galleries, dress-circles, and amphitheatres the exits to the surrounding spaces must be not less than 4ft. 8in. for every 50 persons.

Where, as in the circles, there are steps in the gangways, the nosings of these steps should be made prominent by tacking a strip of white stuff, where there are carpets, along the nosing, so that the step can be easily seen. In the gallery, and sometimes in the upper circle, it is necessary to provide a protecting iron or brass rail fixed on to the "rester" of the gallery front, so as to prevent any one jumping or falling into the auditorium. This is especially necessary where the gallery is very steep, as people rushing in from the top of the gallery, anxious to obtain the front row of the seats, may trip and fall headlong down the gallery and over the front. To prevent such an accident, handrails, as already mentioned, are requisite in the gangways of the gallery.

If the seats are without backs, as is sometimes the case in the pit, intersecting gangways are not needed, as people can walk over the seats, but the discomfort arising from sitting for three to four hours on a form which has no rest for the back is so great, that it is hoped in the future both the pit and gallery will be provided with seats with back rails and divisions, or arm rests. The comfort of the pit has been too long neglected.

Although I have advocated here the adoption of the methods used in Austria and New York for the arrangement of gangways, I must remind the designer of an auditorium that he must at no time lose sight of the interest of his clients, and that he must so devise the disposition of his seating and his gangways as not to produce a loss on the nightly takings; it is true that many gangways mean few seats, and few seats mean small profits; but I contend that an adequate provision of gangways can be obtained without permitting the manager's pocket to suffer. Gangways are frequently of unnecessary width near the stage and not wide enough near the exit; if they were made to widen out in the manner advised in proportion to the number of people using them, I do not think there would be any more serious loss of space than where a gangway is the same width its entire length.

Where the floors of the circles and area are of concrete, provision should be made to secure the seats to the floor by inserting lead or other plugs in the concrete, into which the lugs on the bottom of the legs of the seats can be secured down.

There are many matters of a very minor character, which for all that are sufficiently important to receive the attention of the architect in arranging and furnishing the interior of the auditorium. Carpets, where they are needed, should be so fastened to the floor that they cannot ruck up, and be the cause of anyone tripping or falling over them. Where the floors are stone or concrete, provision should be made for securing the carpets. For similar reasons where there are mats, they should be sunk in squares, so that their upper face is flush with the floor-line. Although carpets, &c., should be secured for the safety of the public, they should be so laid as to be easily taken up and beaten for the comfort of the audience. Carpets and matting, which are frequently used to deaden sound, are often filthy and highly inflammable. A wood-block flooring laid on top of the concrete has neither of these undesirable qualities: it can be easily washed, and when secured to the floor below, not easily burnt; linoleum and kamptulicon are admissible; but a wood-block floor gives a secure fastening for seats and carpets. The use of curtains is sometimes objectionable;

they are frequently hung before the exit doors to prevent draught—which, by the way, is generally caused through inefficient ventilation—they therefore obscure the existence of the exit door, and destroy the virtue of its presence. Where this is done, care should be taken to indicate, in a conspicuous manner, the fact that there is an exit door behind the curtain. Another evil of curtains is, that they are often so long as to drag the ground, and anyone passing out in a hurry runs the risk of treading on them, falling over, and being trodden to death—a small cause but a serious result, showing what care should be given to minute details in the arrangement of theatres.

The desirability of acquainting the occupants of the seats with the position of the exits is self-evident. The London County Council provide for this by their thirty-second rule:—"All exit and other doors used by the public shall be indicated by painted notices in 3in. white block letters upon a black ground. Such notices shall be painted on the doors and walls at least 6ft. 9in. above the floor. The words 'no exit' shall be painted at least 6ft. 9in. above the floor, in 3in. white block letters upon a black ground, upon all doors, in sight of the audience, which do not lead to exits."

The rules as to notices in other countries are somewhat similar, and need not be quoted here. I have before advised the printing of the plan of each section of the seating on the programme, as a means of educating the audience as to the position of the exits, a knowledge acquired in moments of calm which would instinctively become of immense value in moments of panic, and which indeed would tend to allay or effectually prevent panic. It is the thought of the inability to escape which creates the desire to be the first to rush out.

When there are doors with glass panels in them, such as swing doors, or doors to break and check currents of cold air from entering the auditorium, these panels should be protected by bars or grilles across them, as anyone rushing out might put their hands through the glass and seriously injure themselves. Swing doors in the auditorium should not be made so that they cause a noise in closing, especially where they close of themselves. It appears to me that the Norton door check is an admirable arrangement for securing a silent closing of such doors as these in a theatre. The noise of a door slamming is apt to disturb the performance and disconcert the actors.

STABILITY OF WALLS ON SOILS.—VI.

Systematic Methods of Grouping and Concentrating Loads.

THE modern necessities of massive buildings being erected upon weak or compressed soils have developed scientific methods of treating the problems of the distribution of foundations. The permanent structural weights and pressures are systematically equalised, grouped, and concentrated at a convenient number of points in suitable positions in harmony with the main internal arrangements of the building, adapting its forms to its special uses. The various assemblages of weights are reduced to their statical resultants. The supporting points are placed at the common static axes of the contributory loads, with their bases placed geometrically concentric to the axis, and expanded in proportion to the weight of the accumulated load, so as to produce an unvarying safe unit pressure over the area of the underlying soil which shall not exceed its safe permanent supporting power.

Order of Proceeding in Designing Foundations.—It will now be evident that in order to proceed to scientific designing of foundations all the weights and forces involved should receive systematic treatment. For purposes of illustrating the method, we assume that the procedure is naturally resolved somewhat into the following order of occurrence:

1. Having determined the internal arrangement of the building to suit the accommodation required as regards form and dimensions, and the distribution of rooms or apartments on the floor area, including staircases, landings, corridors, internal wells for lighting interior, for lifts, &c., the several floors corresponding in the main points and lines of their arrangements, so that uniformity and concentration of loads and weights and of points of support for all parts throughout the height of the building shall be preserved

symmetrically; economy of materials and duplication of work and of structural parts thus secure considerable economy of cost of execution.

2. *Separating and Limiting the Area and Extent of Fire Insurance Risks.*—The nature and extent of fire risks are greatly influenced by the nature of the intended occupation of the building and the effectiveness of the provisions made in the design for separation of risks by proper division walls carried through and above the roof, by fireproof floors and partitions, and having all means of access of fire between the separate risks effectually stopped according to the regulations of the fire insurance companies. Due attention must also be given to the provisions of the local building by-laws in operation for the time being.

3. Determine the effective (not clear) heights and number of stories, the architectural composition and treatment of the masses of the façade, and any special features, such as pavilions, oriel and bay windows, balconies, verandahs, loggia, engaged columns, pilasters, porticoes, pediments, &c., and the materials thereby involved, the density of which will influence the weights and pressures which have to be supported by the foundations.

4. Determine the various thicknesses, with their respective heights, of the façade walls, with all stone dressings, architectural features, and details, as well as of the main and party-walls, and also the fire and other walls and partitions passing through and above the roof, including all chimney loads, loads from pavilions, gables, gables, dormer-walls, loads from the roofs and gutters, and all appendages thereto.

5. Determine the dimensions and weight of beams, girders, bressummers, &c., adjusted to their several spans, also of fireproof and other floors, stairs, staircases, columns, and stanchions, piers, and posts, with their estimated loads, dead or live, or both, as the case may require, and all sources of load accumulations at points of concentration and discharge.

6. Determine all the loads which are concentrated at the different points of discharge, and whether acting axially or eccentrically upon the columns and structures, piers, &c., together with the weights of all intervening and lower piers, footings, &c. The floor loads include not only the actual structural weight, but also those due to fittings, furniture, machinery, goods stored or warehoused, and also live loads of occupants, according to the intended manner of occupation, being careful to omit nothing which will add to the load at any time imposed by the building upon its underlying soil.

7. We are now in a position to obtain the total loads at all the points of concentration which are to be discharged upon the foundation soil, and to determine the position of the axis of the proper resultant of all the concentrated loads—the forms of the ultimate distribution of the pier footings—duly observing the points of imposition of all abutting loads, such as those of spandrels and transoms in the bays, in fenestrated walls, also those of oriels, projecting cornices, and other projecting features and structures.

8. It is requisite that adequate methods of testing the safe, permanent bearing power of the soil in question should be adopted. These should have in view an investigation of the character of the stratigraphy of the site, and the composition and structure of its petrography. When solid rock is not within convenient reach, and that piling of any description is not desirable, means of ascertaining and utilising the bearing power of the intervening soil should be sought.

Stratigraphy.—Particulars of this are usually obtained by means of auger borings, digging deep wells, or examining existing wells, mine-shafts, deep quarries, earth excavations, railway cuttings, &c., in the vicinity.

Petrography.—The method of treating this branch of the question will depend on the nature of the rock or soil. A practical guide in a simple method of investigating the character of an alluvial soil is that adopted by Mr. A. Waterhouse, R.A., with the foundation soil of the Hotel Metropole, Brighton. Having, by trial holes, dug to a considerable depth, he found that solid chalk was at far too low a level to bed the foundations directly upon it, while all the soil above the rock consisted of a geological *débris* of flint and gravel (of 3in. pieces and smaller) along with chalky clay, and only a little water. The flints and gravel were screened away in sufficient quantity for use in the concrete required in the foundations, floors, &c., and the residue of the finer chalk and clay, by washing, redrying,

and weighing, was found to be about 10 per cent. of the whole mass. From this he judged that $2\frac{1}{2}$ tons per square foot might safely be imposed upon it.

9. Having determined the safe bearing power of the soil per unit load area, then the area of the pier footings—

$$= \frac{\text{Total pier load}}{\text{Unit load area as tons per square foot.}}$$

The square root of the above quotient is the length of the side in feet of a square footing, or if there is a fixed breadth or length, divide by either, gives the corresponding side of the rectangular footing.

Designing Disposition of Foundations.—In the ordinary range of civil and domestic buildings it is seldom that the designing of the footings necessitates the taking account of their capability to resist overturning of the wall, and yet this problem should not be overlooked, for buildings have been overturned by wind force during the process of erection, though in some cases the point of overturning has been at a level above that of the footings, as occurred at Glasgow some years ago. In tall mill or factory chimneys, towers, steeples, and extremely high or exposed buildings, the resistance to overturning becomes a necessity in the design, and we shall therefore consider this problem in its order, but it shall first be considered in its relation to the capability to transverse resistance to the weight of the imposed loads, when the area of the footing base has been increased in proportion to the load, so that the safe unit static resistance of the supporting soil shall not be exceeded. The design of the foundation supporting area and its proper distribution at points of load concentrations will be presently considered.

Designing the Off-sets of Footings in Different Materials.—The off-set of masonry footings is frequently solved as a mere rule-of-thumb problem; but it is more satisfactory to be assured that an off-set is safe for its load than taking it for granted. The all-importance of being assured of safety seems to demand that a sure method of ascertaining it should be at the fingers' end of the designer, for a lamentable failure of the foundations may result from inadequate transverse strength of the footing off-sets under a desire or a necessity to spread the footing base very rapidly within the least height.

By way of illustration, we will consider the first course of footings *ff*, Fig. 15, off-setting

FIG. 15.

under the base of the wall *W*. It will be observed that the part of the footings projecting beyond the faces of the wall act as cantilevers, in which the outer end *f* is free, and the inner end is fixed or rigidly confined under the wall-base. The load and the reaction are uniformly distributed over the projecting area. The reaction *rr*, or *r'r'*, may be the pressure of a lower footing course, or that of the foundation soil, or of a bed of concrete that is frequently interposed between the masonry footings and the soil. *r''r''* are the centre points of the sum of the reactions of both the courses *f* and *f'* outside of the wall-face, but each course must be estimated separately for its respective projection beyond the wall-face. The conditions which regulate the extent of the safe off-sets *ff*, or *f'f'*, are the intensity of pressure expressed in pounds, hundredweights, or tons per square foot, the transverse tenacity of the material used, and the depth *d*, or thickness *t*, of the footing course.

As the pressure is uniformly distributed, it is equal to the load upon the area of the offset concentrated at the centre of the projection, and if this load be $\frac{1}{2}$ the projection it = continued product of $\frac{1}{2}$ th of the modulus of rupture (*R*) in lb. per square inch, the breadth or projection of

MARINERS' REFUGE AT GORLESTON, GREAT YARMOUTH.
H. DUDLEY ARNOTT, ARCHT.

the footing course, and the square of the thickness (ℓ). Let p = maximum projection of footing course, t = its thickness, P = pressure in tons per square foot on bottom of footing course, R = modulus of rupture, which is 18 times the centre breaking load of a level beam of uniform rectangular section supported at both ends. In the shape of a formula, this may be expressed thus—

$$p = \frac{1}{8} t \sqrt{\frac{R}{P}}$$

which gives the maximum rupturing projection. Therefore there must be a safe margin allowed according to the quality of the material and workmanship, and the precision with which the loads have been computed at their full value, static or dynamic, as the case may be. The transverse strength of different concretes, sandstones, limestones, bricks, &c., may range from $\frac{1}{2}$ to $\frac{1}{4}$ lower or higher than the average experimental data of recognised authorities, according to the quality and degree of correspondence of the materials in question with the quality or character of the standards of materials furnishing the data supplied by the experimental authorities, but it must be remembered that all such tests have been obtained with small carefully-selected specimens of excellent quality, free from all flaws and irregularities. The tabulated data is a mean between the highest and the lowest results, which may differ in some materials very considerably, lower or higher.

The following are the projections, in terms of thickness, which may safely be given for good materials of the kinds named. Thus for good hammer-dressed stone in large rectangular blocks, projecting less than two-fifths of their length—i.e., more than three-fifths of their bedding area—being under the course immediately overlying it, and laid in good Portland-cement mortar. For rubble in large, well-bedded stones, laid in good strong mortar, a very little deduction need be made from the projections tabulated, but the pressure above the course must not exceed the safe crushing strength of the mortar. For rubble in smaller irregular-

shaped stones laid in Portland cement, the projection should be very little more than allowed for concrete. If rubble be laid in lime-mortar, then the projection should not exceed half that allowed for cement-mortar.

TABLES OF OFF-SETS OF FOOTINGS.

Materials.	R in lbs. per sq. in.	Off-set in parts of thickness for a pressure on bottom of course of 1 ton per square foot.
Granite	1,800lb.	2-1 times thickness
Limestone	1,500lb.	1-9 " "
Sandstone	1,200lb.	1-8 " "
Slate	5,400lb.	3-6 " "
Best hard brick	1,500lb.	1-9 " "
Hard brick	800lb.	1-4 " "
Concrete: 1 Portland cement, 2 sand, 3 pebbles	150lb.	0-6 " "

Note.—For other pressures per square foot use the corresponding multiplier or fraction of a ton.

The factor of safety of the above is 10.
For other factors of safety use the corresponding fraction of R in applying formula.
(To be continued.)

MARINERS' REFUGE AT GORLESTON, GREAT YARMOUTH.

THIS building, now in course of erection, is situated near the Brush, Gorleston. The site is being built by voluntary contributions, and is a pretty and convenient one, and commands a grand view of the river Yare and North Sea. It is built with local red bricks and black joint, the dressings being of Cossey ware. The roof is covered with plain tiles, and chimney-shafts of red brick. The internal joinery will be of pitch-pine varnished, and the general fittings will include large fireplaces, bath-room, zinc-lined

tables fitted to receive hot water. The bath will be heated by gas; beds will be provided for the comfort of injured persons brought ashore from wrecks, &c. It has been designed, and is being carried out, under the superintendence of Mr. H. Dudley Arnott, architect, Gorleston, Great Yarmouth. The contractor is Mr. J. Y. Cockrell, of Gorleston.

CHIPS.

Mr. T. H. Shipton, late assistant borough surveyor of Tewkesbury, has been elected assistant road surveyor to the Worcestershire County Council.

As a part of the work of doubling the South Devon division of the Great Western Railway, a new tunnel is being driven alongside the old one at Marley, near Brent. The new tunnel is 856 yards in length, is quite straight, and is connected by three openings with the old tunnel. Mr. Lovatt, of Wolverhampton, is the contractor.

A committee has been formed for the purpose of erecting in Worcester Cathedral a memorial to the late Bishop Philpott. £900 has already been raised in the diocese, and the work has been assigned to Mr. Thomas Brock, R.A., for execution.

Dr. Danford Thomas, on Saturday, held an inquest at Kilburn concerning the death of William Williams, 65, lately residing at 11, Brondesbury Villas, Kilburn. Deceased, a slate merchant, carried on business at South Wharf-road, Paddington, and on the 22nd ult. went to the premises of Mr. Preyer's saw mills, of Kilburn, and accidentally fell down a flight of steps leading to the engine-room. He died on Wednesday from injury to the brain. The jury returned a verdict of accidental death.

The Mayor of Southport will on the 29th lay the foundation-stone of a new infirmary, which will cost, exclusive of the five-acre site, which has been presented, over £13,000. Mr. C. Sydney Ingham, of Manchester, is the architect.

The Manorhamilton Board of Guardians have discharged Mr. Henry Cummings, appointed by them as engineer and clerk of works, on the ground that he supported the Conservative candidate at the recent county election.

MANCHESTER TECHNICAL SCHOOL: SELECTED DESIGN.

LAST week we described at some length all the more important designs sent in for this great work, and to-day we illustrate the selected designs by giving the two principal plans, and the general perspective views showing the main front in Sackville-street, with the return façade facing Whitworth-street. Messrs. Spalding and Cross, of Queen Victoria-street, London, are the architects. There can be no doubt as to the superiority of their elevation over those to which the other premiums have been awarded, while their plans, as can be readily seen by our accompanying reproductions, are well balanced, well lighted, and practically arranged. In some respects the elevation, in its balance of parts, carries out the same idea which is observable in the City of London and Technical Guilds Institute in Exhibition-road, Kensington, which Mr. Alfred Waterhouse, R.A., erected ten years ago. The Manchester building, however, is treated with perhaps greater breaths of wall space, the fenestration being grouped together more decidedly.

APSE OF COUTANCES CATHEDRAL.

THE apse of Coutances is one of the finest examples known of this method of terminating the east end of a church—a method which, while common enough in France, is comparatively rare in England. Together with the rest of the Cathedral, it is in the Early French style, dating from the early part of the 13th century. The effect produced by the curved aisles, with their maze of arches and columns, is superb, and must be seen to be thoroughly appreciated. To the absence of the usual partition walls of the side chapels must be attributed in great measure the remarkable beauty of this apse, the choir being, in fact, surrounded by a double ambulatory, divided by columns. The round abacus used here is a peculiarity worth noting. In contemporary work in England, the square abacus, which disappeared with the Transition, would never be found; but in France the square abacus continued more or less through all the styles, and constituted one of the principal points of difference between the Gothic architecture of the two countries. It is only occasionally, as here at Coutances, that the round abacus is to be found.

CRYPT DE L'AQUILON, MONT ST. MICHEL.

OF all the parts of that extraordinary place, Mont St. Michel, perhaps none are more interesting

than those ancient portions which formed part of the primitive monastic buildings, and of which the illustration shows that part known as the Crypte de l'Aquilon. They date back to about the year 1020, having been founded by Duke Richard II., grandfather of the Conqueror, some fifty years before Norman architecture was practised in England. The part seen in the illustration, however, is later than this, having been built by Roger II., the eleventh abbot, between 1106 and 1123, and is in the Norman style, the abacus being of the characteristic Norman shape. The stairs lead up to the ancient promenoir or cloister of the monks, of which the Crypte de l'Aquilon forms the sub-structure. These communicate with a vast series of buildings constructed by Robert de Torigni towards the end of the 12th century, and extending all round the north side of the mount. They included the infirmary, hostelry, the chapel of St. Etienne, with its far-famed Black Virgin, the dungeons, and the monks' cemetery—a dismal vault of vast proportions, capable of holding generations of Benedictines, built in the heart of the rock, and in perennial darkness. We are indebted to Commander Charles E. Gladstone, R.N., for these capital photographs. Others, by the same hand, will follow at an early date.

"SUNFIELD," DAISY HILL, BRADFORD.

THIS house has been erected at Daisy Hill, a pleasant suburb of Bradford, and commands an extensive view of the hilly country to the south and west. It is built of local stone, with sandstone dressings from Guiseley, and is roofed with green Westmoreland slates and red-tile cresting. The works have been carried out by local builders from the designs of Mr. Herbert Hodgson, A.R.I.B.A., of Bradford.

DISTRICT CHURCH, BIRLING, KENT.

THE view and plan are of the west end. The narthex opens into the nave by a wide arch. Carried on an arcade at the springing level of this arch is a ringing-stage, the wire bell-ropes passing through guides in the roof of the narthex. The ringing-floor is reached by means of a stair entered from the outside. Mr. Hubert Bensted, F.R.I.B.A., of Maidstone, is the architect of the work illustrated.

THE MARIA GREY TRAINING COLLEGE, SALUSBURY-ROAD, BRONDESURBY, N.W.

THIS building is pleasantly situated upon a site of about an acre in extent near the Queen's Park, and within easy walking distance of Kensal Rise and Brondesbury railway stations. It has been erected to provide a suitable home for carrying on the work of the Maria Grey Training College and the High School for Girls and Kindergarten, which were formerly located in Fitzroy-street and Fitzroy-square, W. The college schools are now under one roof, and designed to accommodate about 75 day students and 200 children. On the ground floor are library for students, 31ft. by 22ft.; luncheon room, 28ft. by 23ft.; kindergarten rooms, 17ft. 3in. by 19ft. 6in., and 21ft. by 19ft. 6in.; ample and well-lighted cloak-rooms; kitchen, 19ft. 6in. by 17ft. 3in., with scullery, larder, heating chamber, and offices. W.C.'s and lavatories for students and pupils, and a stone staircase, are arranged in a detached block near the pupils' entrance. On the first floor (school) are an assembly room 60ft. by 28ft., five classrooms of various dimensions, one division room, rooms for the principal and secretary, waiting-room, &c. On the second floor (college), are teachers' room, studio, 31ft. by 22ft.; lecture-room, 24ft. by 21ft.; three classrooms, and laboratory, 22ft. by 18ft. On the third floor are five music-rooms and two bedrooms. The principal, and for students, entrance, owing to the nature of the site, is across a raised footway from Salusbury-road to the first-floor level, and a wide staircase at the entrance gives access to every floor. The pupils' entrance is on the ground floor, approached by steps from the Chevening-road. At this entrance also is a staircase, giving access to each floor and to the lavatories. The building is faced with red bricks and covered with Broseley tiles. All the windows have reversible sashes, which can be cleaned from the inside; all the floors are polished. The interior is warmed by ventilating grates, supplemented by hot-water pipes of medium pressure. The building has been erected for the Council of the Teachers' Training and Registration Society, at a cost of about £10,000. The school portion has been occupied since Easter; the work of the

training college will recommence early in September. The architect is Mr. J. Osborne Smith, F.R.I.B.A., and F.San.Inst., of 34, Southampton-street, Strand; and the builder Mr. Chas. Wall, of Chelsea.

"BUILDING NEWS" DESIGNING CLUB: A ROSEWOOD CABINET.

THIS design for a drawing-room piece of furniture was sent in by "Vulcan" last June according to the conditions issued for the guidance of the members of our Designing Club, and we awarded him the second place in this competition. An illustration of the design placed first figured in our issue for June 10, when a review of all the drawings submitted for this subject was given. We then said of this design: "'Vulcan' gains little by introducing the two figures right and left of his cabinet, and the vertical lines of the upper part seem needlessly numerous. It is a commodious piece of furniture, but would be more useful if another shelf had been introduced for the display of small articles in the principal cupboards. For rosewood there seems a little too much timber in the design." The illustrations of designs for a shooting-box in the Highlands will appear very shortly. This was the concluding subject for the past session of the club's work. The new session will begin early in November.

CONSTRUCTIONAL DRAWINGS: VI.—A ROOF IN STEEL.

(See description and further sketches on p. 416.)

CHIPS.

The Jewish synagogue, Fountains-road, Kirkdale, Liverpool, was reopened on Saturday, having been redecorated at the hands of Messrs. Raffle and Campbell, at a cost of £300.

A new Wesleyan chapel in Oldfield Park district, Bath, was opened last week. It has cost nearly £2,000, and is built of stone. The chancel seats 350 persons, and beneath it is a schoolroom and infants' room.

The Chatham town council have instructed their borough surveyor to prepare plans for a technical institute at the east end of High-street, at a cost of £2,500.

The excavations for the partial rebuilding of Sir Joseph Williamson's School at Rochester have laid bare the base of the north tower of the east gate of the ancient fortified city.

On Saturday a monument to the late Rev. Robert Shaw Hutton, D.D., minister of the parish of Cambusnethan for 40 years, was unveiled in Cambusnethan Cemetery, Wishaw. The monument is of red sandstone and granite; it is in the Gothic style, and has been sculptured by Mr. Cumming, of Wishaw, from drawings by Mr. Wallace, architect, of London.

Prof. Reginald Stuart Poole, who for nearly forty years has been connected with the department for coins and medals, will retire from the British Museum at the close of the year. On the retirement of Prof. Sir Charles Newton, K.C.B., from the professorship of archaeology at University College, London, Mr. Poole was elected his successor.

The Earl of Rosebery will open the Borough-road Polytechnic, near St. George's-circus, Southwark, on Friday afternoon next, the 30th inst.

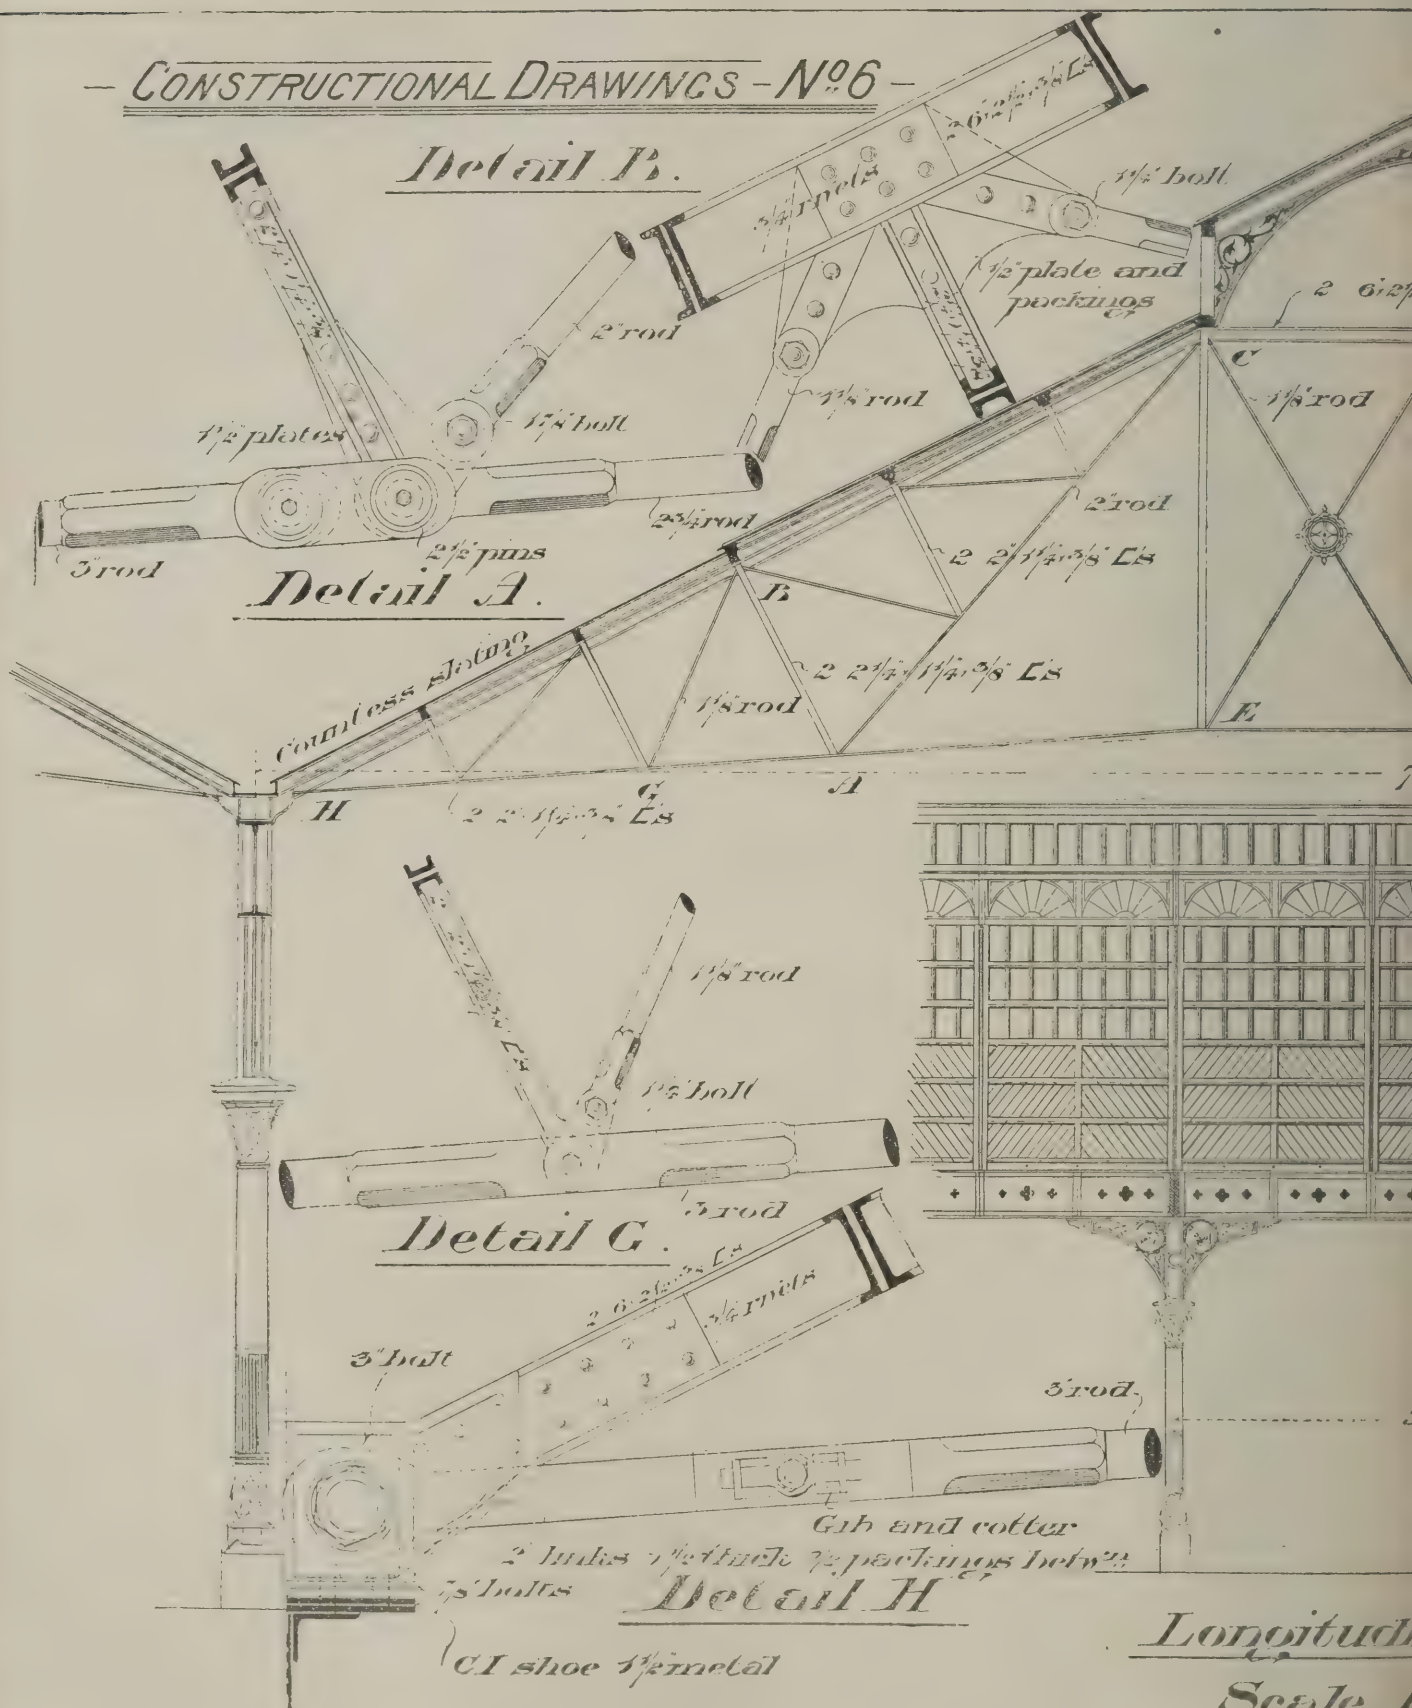

Mr. John Thomas Mulvany, C.E., formerly district engineer to the Board of Works in Ireland, has recently died at Kati Kati, New Zealand, aged 71. He was the last surviving son of the late Thomas J. Mulvany, R.H.A., of Dublin.

A brass tablet has been fixed on the staircase of the Whitechapel Free Library and Reading Rooms bearing the annexed inscription: "This tablet was placed by the Commissioners to commemorate the generosity of J. Passmore Edwards, Esq., in defraying the cost of erecting this building. 1892."

The external restoration of the Lady Chapel at the east end of Lichfield Cathedral is now approaching completion, after having been in hand for some years. The stonework has been renewed, and the stained-glass windows have been taken out and re-leaded. The niches, which originally contained figures, have now all been filled, the last three (by Mr. Ingram, London) having been put up this week. Mr. R. Bridgeman has carried out the restoration.

The improvement commissioners of Leek have resolved to advertise for competitive plans for dealing with the Red Lion property and the site available for a covered market, including early provision for a butter market, a premium of £25 to be offered for the selected plan, and £10 for that which in the opinion of the board is the second best.

WAYSIDE NOTES.

THE autumnal meeting of the Iron and Steel Institute has been held this year at Liverpool, and commenced on Tuesday last, when Sir Frederick Abel, as President, addressed the members. One of the most interesting papers read at the meeting was that by Mr. T. H. Greathead, C.E., the engineer of the City and South of London Railway, dealing with the overhead railway now in course of construction at Liverpool. From this we learn that the railway when complete will be worked by electricity, many of the objections to the New York Overhead Railway being thus removed. The works are evidently now far advanced, since it is intended to open the line for traffic very shortly now—perhaps at Christmas.

The new railway—the first of its kind in this country—is composed almost entirely of wrought iron, the line traversing almost the whole length of the Liverpool Docks, a distance of about six miles. The railway consists generally of plate-iron girders, supported on channel iron columns, and carrying an iron flooring upon which the permanent way is laid direct, without the usual intervening ballast. The normal spans are 50ft., but some are 100ft. with girders of special construction. The columns are let into cast-iron sockets, bedded in and bolted to masses of concrete forming the foundation. Excepting in the case of some half-dozen spans, the line has been constructed without the use of scaffolding, and with very little interference with traffic. Fifteen stations are provided, and built upon iron girders and columns, the platforms being 115ft. in length by 12ft. wide, and 3ft. above the level of the rails, while access is gained from the street by four staircases. A train will consist of two carriages, each to seat 56 passengers, apparently answering somewhat to the description, so far as regards general arrangement, of the cars on the City and South London Railways. There will, however, be two classes. A loaded train is calculated to weigh 40 tons. The trains will be lighted by electricity, and fitted with the Westinghouse brake. A novel feature is a system of automatic signalling at all the intermediate stations (which, apparently, are to consist merely of platforms), the signals to be electrically worked by the trains themselves. The total cost of the line has been about £85,000 per mile.

Mr. Greathead says that there will be no more noise on this line than on any other railway. This is contrary to what one would suppose, considering the metal framework supporting the permanent way, which should suffer much vibration. Probably the noise will be more like that of a train upon a metal bridge. Anyhow, some of the Liverpool horses may at first raise objection to the new mode of aerial transit. I scarcely imagine the system will find great favour in this country.

The Inman steamers are in the near future to run from Southampton. Arrangements have been fully completed. In consideration of the benefit that the line will bring to the town, the South-Western Railway Company are getting the land for the new docks at a wonderfully cheap rate—nominal, in fact. The corporation have offered the company fifty acres of mudland at the rate of £20 per acre. Messrs. Lucas and Aird are to carry out the contract, and the firm commenced preliminary operations on Tuesday. As soon as the formal consent of the corporation has been received, the work will be pushed forward with the utmost despatch, the first Inman liner being expected to sail from Southampton in March. I understand that if this work of dock-making is completed as soon as is anticipated, it will stand out as a record of its kind.

Ship-building seems really to be at an extraordinarily low ebb. Only a few weeks ago I alluded to the state of the yards of some of the east-coast firms, and now fresh complaints come from Glasgow and the Clyde. On Monday last it was reported that out of 148 berths on the Clyde only 49 are occupied with ships in progress, while it was estimated that 5,000 men were idle. In Dumbarton the riveters—usually the best-paid workers in the trade—are offering themselves as labourers. Many have gone to Barrow, Belfast, and the east coast in search of employment; but, unfortunately, so many yards in these

places are also slack of work at the present time. There may be some slight relief to the Clyde firms now that two new steamers have been ordered for the Inman line. The vessels are to be of 9,000 tons each, and one will be built by Messrs. Napier, of Govan, and the other by Messrs. Denny Bros. and Co., Dumbarton. I trust that business may quickly mend with ship-builders; it is painful to think of so grand an industry in distress. Ship-building has frequently moved the poet to song. I cannot, by the bye, call to mind any such thing having occurred in connection with modern building proper, unless it has been in the A.A. *soirée* farces!

Bristol is anxious to establish a line of Transatlantic steamers. The town council held a sitting early this week to discuss a proposal to construct new docks at Avonmouth, together with a landing pier, to admit of Atlantic liners reaching the port at any state of the tide, and a railway along the quays, the whole at a cost of about £1,065,000. The situation of Avonmouth offers some advantages; but the Bristol Corporation would find it immensely difficult to get trade out of its old routes. An exceedingly bold move might be successful, but it would have to be very bold indeed. Milford Haven, again, has long been pointed out as the most suitable port for the arrival and departure of American steamers, and there is little doubt but that a bold spirit, with ingenuity and enormous capital, could establish a line of Transatlantic steamers there.

The Curriculum for Session 1892-93 of the Architectural Association has come to hand, and foreshadows a busy year for those who take part in the students' work, either as learners or instructors. It is compactly arranged, and not being of unwieldy size, students can without inconvenience keep it in their pockets ready for instant reference. The time-table serves to remind older members that the *Conversazione* will be held on Oct. 7, and the presidential address will be delivered at the annual general meeting on Oct. 21.

Mr. G. A. T. Middleton, the energetic secretary of the Society of Architects, delivers a series of lectures on "Architecture and Building" at the St. James's Hall, during the next three months. On Mondays, commencing Monday, Oct. 3, a series of ten lectures on "Architectural History and Ornament" will be given; and on Fridays, commencing Friday, Oct. 7, a course of ten lectures on "House Sanitation." The syllabus of the former shows a most interesting course of much value to students of architectural styles, and that of the latter embraces an exhaustive survey of sanitation and hygiene. The lectures will be delivered at 7 p.m., and those on architecture will be fully illustrated by limelight views.

GOTH.

THE ALHAMBRA ALTERATIONS AND DECORATIONS.

THE partial reconstruction of the Alhambra was entered upon eight weeks ago, and is now concluded, the theatre having been reopened this week. The grand circle balcony has been advanced several feet into the house, giving more seating room on the first tier, and greater space at the back. In redecorating the grand lounge and stalls, the Alhambresque style has been somewhat intentionally disregarded, in order to get a lighter effect. The whole of the decorative tone is therefore kept cream, white, and gold, with a little grey-blue to relieve it. The frieze above the mirror panelling is a heavy raised material, decorated specially for the work; the mirror panelling has been carried round the two ends of the circle to complete the whole. The ceiling has been levelled with fibrous plaster to hide the many girders which intersected it and caused a heavy, ugly appearance, and is now painted a light blue with gold stars. The fronts of the balconies and proscenium have been entirely redecorated, and the private boxes draped with amber brocatel. The iron columns are covered with raised gilded material, and the panels of the doors of the private boxes are filled with a similar material. The Foyer has also been redecorated in the same light manner. The five window spaces have been filled with Arabesque screens and stained glass, having electric lights behind them. But the great altera-

tion, as before mentioned, has been in the grand circle balcony, which has been advanced 6ft., giving additional seats and passage room, and a much improved view of the stage. The upper circle balcony and bar, on the second tier, and the two staircases have been renovated, whilst the grand circle staircase and entrance hall to private boxes and stalls have been redecorated. The theatre has been recarpeted and upholstered in colours and material to suit the general scheme, and a complete system of electric lighting, entirely new, introduced. The decorations are by Messrs. Campbell, Smith and Co. The plastic ornamentation is by Messrs. George Jackson and Son. The works have been carried on, under the supervision of the architects, Messrs. Clark and Pollard, without closing the theatre a single night.

CHIPS.

The Bridgewater highway board have appointed Mr. E. P. Batter, of Richmond, Surrey, as district surveyor, and Mr. H. C. Ransley, of Worthing, as assistant surveyor.

The new Wesleyan Church of St. John, in Langworthy-road, Weaste, Manchester, was opened on Friday. The church, school, and land have cost £6,600, and the sittings are for 700, against 300 sittings in the chapel now replaced.

Another step has been taken in the scheme of restoring St. John's Church, Perth, the congregation and minister having formally agreed to the removal of the galleries.

The tender for the erection of a large block of maltings, including a barley drying kiln, in Northgate, Newark, for Messrs. Gilstrap and Earp, has been taken by Messrs. Mackenzie and Son, King's-road, Newark. The amount is £22,000, which is the largest private undertaking yet begun in the town. The sub-contracts are:—Brickwork, Messrs. George Brown and Son; plumbing, Mr. S. Ironmonger; painting, Messrs. Harston and Son, all of Newark. The malting will be a 250 quarters steep. Messrs. Evans and Jolly are the architects.

The Crown Court and offices, Lancaster Castle, have just undergone considerable alteration and improvement at the hands of Mr. E. Howard Dawson, A.R.I.B.A., and Assoc. San. Inst., of Lancaster. To provide direct access from a new waiting room for witnesses to the court, one of the old Roman walls of the castle, 12ft. in thickness, had to be pierced. The principal work has been satisfactorily executed by Mr. Casson, joiner and cabinet maker, and Messrs. Seward and Co., plumbers, of Lancaster, at a cost of about £500.

A brine bath department is being added to the corporation public baths at Stafford, and the Turkish baths are being improved. Mr. C. J. Nevitt is the general contractor, and Messrs. Rudge and Griffith have supplied the baths and fittings.

Mr. F. H. Talloch, A.M.I.C.E., Local Government Inspector, held an inquiry at Bodmin, on Friday, respecting the application of the urban sanitary authority for permission to borrow £1,388 for works of street improvements and purposes of public walks and pleasure grounds. No objections were offered to the proposals, which were explained by the borough surveyor, Mr. J. Oliver, and by the town clerk.

The parish church (St. David's) within the precincts of old Llanthony Priory is to be restored. Mr. J. James Spencer, of Abergavenny, is the architect.

New schools are about to be added to the Congregational church in Wood-street, High Barnet. The contractor is Mr. S. F. Holliday, of Stamford, and the cost will be about £1,000.

The sum of £800 has been raised for a memorial in Peterborough Cathedral to Dr. Magee, the late Archbishop of York, and the committee have accepted the design of Mr. John L. Pearson, R.A., for the cenotaph. The sculptor commissioned to execute the memorial is Mr. James Foreyth, of Hampstead.

A north wing is being added to the County General Infirmary at Stafford, from the plans of Mr. Aston Webb, of London. The elevation harmonises with the older part of the institution, but is raised on low arches. Mr. F. Espley is the contractor, and Mr. H. T. Peabworth the clerk of works.

Memorial-stones of a Wesleyan chapel were laid at the corner of Willoughby and Hampden roads, Hornsey, on the 15th inst. The building will be Early English in style, and built of red bricks with stone dressings. Mr. Robert Curwen, of Palmerston-buildings, is the architect. In addition to the chapel, which will seat nearly 1,000 persons, are to be built an infants' class-room, additional vestries, and a chapel-keeper's house; the whole group being estimated to cost £6,000.

RESIDENCE AT CATTON, NEAR NORWICH.

THIS house, with stables and carriage-house at the rear, has just been erected for Mr. A. W. Bell by Mr. J. Evans, builder, of Norwich and South Walsham, from designs and under the supervision of Mr. Albert C. Havers, architect, Norwich. The house faces the high road to Norwich, and commands extensive views of the city. The ceilings of the dining and breakfast-rooms are panelled in plaster. There are altogether eight bedrooms, with two dressing-rooms, bath-room, and w.c., &c.

AN EXHIBITION OF ARCHITECTURAL PHOTOGRAPHS.

THE series of Somersetshire photographs opened yesterday by Mr. J. L. Robinson, R.H.A., at the Royal Architectural Museum, Tufton-street, Westminster, enables the visitor to see wherein the rich screens and elaborate bench-ends, with other woodwork in the churches of the Taunton district, contrast, rather than compete, with the, perhaps, finer, and, in some respects, more satisfactory specimens of the same date and character to be found in Norfolk and Suffolk, more particularly near King's Lynn and away in the country about Norwich. West Somerset is by no means so wealthy in mansions of historic interest as the country round Yeovil, or even nearer Wells. Indeed, the beauty of the Ex-moor scenery and the grandeur of the Quantocks must be reckoned as the chief attractions of West Somerset. Old Cleve Abbey, of which Mr. Robinson shows some nine or ten pictures, is, of course, in its way almost unique, and is certainly a most delightful example of typical English monastic architecture in many respects unsurpassed elsewhere. The convent garden side of the refectory figures to an enlarged scale in print 39, being much from the same point of view as the sketch published in our pages on August 19th last. Two of the most admirable prints from this place here given are 71 and 74. The first shows a magnificent old tree leafless and dead

by the side of an equally fine specimen in full foliage. The second gives a sketch of the "Holy Rood Water," with cattle cooling themselves in the stream. Dunster is represented well by photographs 7, 8, 9, and 10, also by 65 and 66 in the smaller series. Nothing could be better than Mr. Robinson's sheet of the great screen at the parish church, with its wonderfully intricate carvings on the main cornice over the vaulting supporting the loft. The side screen, too, leading to the south aisle of the choir is exquisitely rendered. The Yarn Market in views 10 and 37 makes a capital picture. Two other successful enlargements are 40 and 40A of the interior of East Quantoxhead Church, illustrating the pulpit, screen and pewing in useful and suggestive detail. The interior of St. Decuman's Church, as we already have said when describing the Architectural Association excursion visits in particular last month, is especially noticeable for its barrel-vaulted roofs, which have singularly pretty cornices and ribs. No. 38 as here enlarged carefully depicts part of these; but they do not surpass for excellence of workmanship such church roofs as those at Knapton and Mildenhall in East Anglia. No. 60 gives a general view of the nave and chancel. The towers of St. Mary's Taunton, Ruishton, Bishop's Lydeard, Kingston St. Mary, and Staple Fitz Payne are all done justice to in the best style and from the best points of view. Minehead supplies first rate and useful details in the prints 59 to 63, those of the font, chest in vestry, and Jacobean altar table being specially worth notice. Spaxton and Blackmoor farms, Combe, Sydenham, and Cothelstone manor houses, Nettlecombe Court and East Quantoxhead are among the houses which are here so well recorded. For successful photography the staircase of the last named building may be here singled out for reference. Creech St. Michael makes quite an artistic picture (No. 6), while the pulpits in the stocks under the ancient yew tree in the same churchyard (No. 58) show how far architects can sink in the social scale from all appearances. Bridgewater church comes out well in prints 76 and 77, and Poundisford Park is done justice to by Nos. 4, 53, 54, and 55. That of the old

lead tank next the entrance is simply a perfect sun print, with the two water drinkers giving the cistern scale. Bishop's Hull supplies pretty pictures, and the large groups from Cannington leave nothing to be desired, giving the best possible results with the material available. Chard supplies some of the best subjects in this series of pictures, such as the Chough Inn, the old Guildhall where Judge Jeffreys extended mercy! the Grammar School, and other houses with their quaint old porches in the High-street. The views, too, in the churchyard are worth seeing. Ilminster, which has a fine but very Late church with a central tower of the type of St. Cuthbert's at Wells, is a very interesting and cathedral-like building (125, 126, 127), and as Mr. Robinson visited Wells on leaving Taunton, the present series includes several views from that exquisite cathedral. Nos. 29 to 34 furnish large pictures, and 128 to 131 smaller ones. That of the market place is particularly charming, and so is the view of the cloisters and western tower. No. 133 shows the courier of the party, who has a face like a Gothic gargoyle. The exhibition will remain open at the Museum till the occasion of the A.A. opening conversazione early in October.

Mr. Ernest A. B. Woodward, for the past 13 years of the water engineer's department, St. Helen's, Lancs., who was recently appointed water engineer for the Wolverhampton county borough, was on Friday night the recipient of a testimonial from the officials at St. Helen's Town Hall. The testimonial took the form of 23 valuable works on water engineering, building construction, and similar subjects, each bearing a suitable inscription.

A new Free Presbyterian church is about to be built in Morningside-road, Edinburgh, from plans by Mr. Hippolyte J. Blanc, A.R.S.A. The church will be Renaissance in style, and will cover an area of 98ft. by 50ft., internal measurements. It will have shallow galleries on three sides. Behind the main building will be a hall, children's class-room, vestry, session-room, and caretaker's house. The church will afford accommodation for upwards of 800 sitters, while the hall will be seated for from 200 to 800. On one side of the elevation a campanile tower will eventually be carried to a height of 180ft. The total cost will be about £8,000.

Building Intelligence.

GUILDFORD.—The foundation stone of the new borough police-station in North-street, Guildford, was laid by the Mayor on Wednesday week. The building will be in the Classic style, with separate entrances to the police-station, the superintendent's house, and the private apartments. The front of the building will be of Portland stone and red brick. On the ground floor will be a charge-room, public office, superintendent's private office, and a small room for the weights and measures department. The ten cells, which will be lined with glazed bricks, and the constables' room are to be in the rear, from which a passage of about 100ft. long will communicate with the town-hall. Prisoners will be conducted along this passage, which passes beneath the jury box into the dock. On the first and second floors of the building will be the superintendent's private house, with apartments for a married constable in the rear. The contract for the buildings is for £5,775, and the works, which commenced in May of the present year, are to be completed by March 25, 1893. Mr. William G. Lower, of Guildford, is the architect, and Mr. Robert Wood the builder.

PATRICROFT.—The guardians of the Barton-upon-Irwell Union some time ago purchased the old mills belonging to the Messrs. Waddingtons, which adjoined the present workhouse, and, having made arrangements to erect the new buildings by instalment, have let the contract for the largest portion of the buildings, for aged and infirm pavilions for the administration buildings on Wednesday week, to Messrs. Southern and Sons, by public competition, for the sum of £16,250. When these pavilions are completed, they will be temporarily occupied by the inmates now in the hospital until the new building for them is erected upon the site of the old hospital buildings. The total accommodation, when completed, will be for about 500 inmates. Messrs. Mangnall and Littlewoods, of Manchester, are the architects, whose plans were recommended by the Local Board from competition designs by several architects.

SHEFFIELD.—New printing and publishing offices have just been completed for the proprietors of the *Sheffield Independent*. The style adopted is a free treatment of Early French Renaissance, and the building is faced with Huddersfield stone. The building is T-shaped on plan, the head, next Fargate, being utilised as shops and offices, and the tail as printing works, six floors in height. Messrs. Flockton and Gibbs, of Sheffield, were the architects, Mr. R. Hoskin, of Sheffield, was the consulting engineer, Messrs. William Ives and Co., of Shipley, were the general contractors, and Mr. George Malpass was the clerk of works.

SMALL HEATH, BIRMINGHAM.—The foundation stone of a permanent church of St. Oswald was laid on Saturday at Small Heath, near Bordesley. The present iron church, which will hereafter be utilised as a school, seats about 260, and it is proposed to erect a church of brick and stone, with 620 sittings. The architect is Mr. W. H. Bidlake, M.A., of Birmingham, and the church will consist of a chancel, a nave, and aisles of six bays. On the north side of the chancel there will be an organ chamber and clergy vestry, and on the south side will be a transept and the choir vestry, the two vestries being connected by a passage behind the altar. The walls will be finished in Leicester sand-brick, with Bath stone dressings; the nave piers will be of Hollington stone, and the roof will be tiled. The style adopted is that of the Transition from Early English to Geometrical Decorated. The portion of the work at present undertaken consists of the whole of the east end and four bays of the nave and aisles, with a temporary west front. The design provides also for the erection, by-and-by, of a tower and spire. The builder is Mr. T. Rowbotham, of Small Heath, and the estimate is £4,823. The portion of the church now being built will accommodate 460 worshippers.

WEST HAMSTEAD.—A new synagogue in West End-lane was opened on Saturday. It has been built by Messrs. John Allen and Sons, from the designs of the architect, Mr. Delissa Joseph, of Basinghall-street, E.C. The principal elevation, which is Romanesque in character, has been carried out in red brick and red stone, and comprises a great central tower flanked by secondary

towers, containing the staircases. The building has been planned upon a spacious scale, and is provided with seven exits, all the doors of which open outwards. The main building is in the form of an octagon, the corners of which are occupied by columns carrying the gallery, and from the tops of the columns spring the ribs which form the dome, which is constructed of steel. The gallery is placed in the aisles, which follow the lines of the octagon. The ark, which is in the form of a domed temple, is placed in an apse recessed from the eastern side of the octagon. The choir is at the back of the ark, the voices reaching the synagogue through wrought-iron grilles. Immediately in front of the ark platform is the reader's platform, reached by two staircases, describing quarter-circles, the pulpit being in front of the reader's platform, the whole of the arrangement being new to London. Cloak-room accommodation is provided at each level. The scheme of decoration is pure white throughout. The building is lighted by two ranges of windows and by clerestory lights. The capacity of the building is for 656 sittings, and it has cost £11,000. We illustrated the synagogue by a plan, and exterior and interior views, in the *BUILDING NEWS* for Dec. 11, 1891.

COMPETITIONS.

MANCHESTER.—The Manchester school board have selected in competition plans for four new schools, and have appointed their authors as architects. They are: For the Cheetham Higher Grade School, Messrs. Royle and Bennett; for the Ardwick Higher Grade School, Messrs. Maxwell and Tuke; for the Openshaw School, Mr. H. E. Stelfox; and for the Burgess-street Infants' School, Messrs. Preston and Vaughan.

NEW CHAPEL, GORING, OXON.—In a limited competition for building a new chapel at Goring, the designs by Messrs. Cooper and Howell, of Blagrove-street, Reading, were unanimously chosen. They have been instructed to proceed with the work.

SOUTH SHIELDS.—The name of the assessor in the South Shields Board School competition should have been given by us on p. 384 last week as Mr. William Landless, of Belmont-grove, Clarendon-road, Leeds.

SHEFFIELD.—At a meeting of the Abbeydale church extension committee, held on the 14th inst., Mr. Ewan Christian's report as assessor was read on the plans submitted in competition for the new church. The committee chose the plans of Mr. Joseph Norton, of St. Philip's-road, Sheffield, which had been favourably mentioned by Mr. Christian. The new church is to provide seating accommodation for 730 people. It will be built of stone, Early English in style, and will cost £6,000. The site was purchased some time ago, and an iron mission church stands on the ground which will eventually be occupied by the more substantial structure. Already the sum of £2,000 has been raised towards the cost of the building.

CHIPS.

As memorials of the Raimes family, an oak pulpit, lectern, and prayer-desk, treated in the Decorated style, have been placed in the church of St. Helen at Wheldrake, near York. The work is the production of Mr. J. Roddis, of Birmingham.

William Troman, builder and contractor, of Old Hill, near Birmingham, committed suicide on the 15th inst., by hanging himself in his carpenter's shop. Deceased was about forty-five years of age, and leaves a widow and four children. At the inquest it was shown that he was greatly harassed by pecuniary troubles, and a verdict of suicide whilst suffering from temporary insanity was returned.

St. Dunstan's-in-the-West in Fleet-street was reopened last week after internal decoration, carried out by Messrs. Campbell Smith and Co.

The foundation-stone of Church schools at Ladock, near Grampound Road, Cornwall, was laid last week. Mr. F. W. McCoskrie is the architect, and Mr. John Crocker the builder.

Mr. S. J. Smith, Local Government Board Inspector, opened an inquiry on Tuesday at Manchester respecting an application by the Corporation to borrow £60,000 to purchase Rampton Manor Estate, Nottingham. The estate, if purchased, is to be used for the treatment of a portion of the Manchester sewage. The application was opposed by the local authorities of Retford and other places.

Engineering Notes.

THE TOTTENHAM AND FOREST GATE RAILWAY.—This important suburban junction line, the joint undertaking of the Midland and London, Tilbury, and Southend Railway Companies, is in course of construction. The line, which is six miles four chains in length, commences by a junction with the Tottenham and Hampstead Railway at the South Tottenham Station, and passes between the great reservoirs of the East London Water Company, into Walthamstow. It is then carried through Leyton, Wanstead, West Ham, and East Ham, finally making a junction with the Tilbury line at Forest Gate near Romford-road. The line passes through a populous district, which necessitates the demolition of 343 houses, and as one-fifth of these were artisans' dwellings, the company has had to build 70 new houses under the clauses of the Act of Parliament providing for the rehousing of the working classes. The line also passes through the grounds of five old Essex mansions, four of those formerly occupied by City merchants, and the fifth the Royal Lodge at Leytonstone. The short line crosses so many streets and roads that there are 72 steel bridges, absorbing about 4,000 tons of Siemens-Martin steel. Of these bridges 15 are over and 57 under bridges of various spans and types, no two being alike, while most of them are skew bridges. The line for about half its length is carried on embankment and in cutting, but three miles of it consists of a viaduct of brickwork arches each of 30ft. span. The gradients throughout are easy, and the curves good. Concrete is largely used in construction, especially in the retaining walls. There will be five passenger stations, and four goods and coal depots on the line. The stations will be at Black Horse-road and Shrubland-road, Walthamstow, respectively; Leyton High-road, Leytonstone High-road, and Wood Grange-road, Forest Gate. The construction involved 81,894 cubic yards of brickwork, about 4,000 tons of steel and ironwork, exclusive of rails and permanent way, and over 300,000 cubic yards of excavation. The contract amount is £264,422, exclusive of station buildings. Nearly 1,000 hands are engaged on the works, together with four locomotives and a number of steam cranes. The engineer of the railway is Mr. Arthur C. Pain, M.Inst.C.E., of Westminster, the resident engineer being Mr. Arthur Nunn. The contractors are Messrs. Lucas and Aird, whose agent on the works is Mr. Henry Turner. The line will be open for traffic in September, 1893.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

GLASGOW ARCHITECTURAL ASSOCIATION.—A visit was paid on Saturday by a party of the members to Mugdock and Bardowie Castles, by kind permission of the occupiers. A meeting was held in the Rooms, 114, West Campbell-street, on Tuesday evening, the president in the chair. Mr. Wm. Fraser, A.R.I.B.A., read a paper on "Domes, and their Construction." After running over general points of construction, he noted the chief features of interest in the following well-known domes—viz., the Pantheon, St. Sophia, the Duomo, Florence, and St. Paul's, London. Mr. Robertson opened the discussion which followed.

St. Paul's Church, Caerfallwch, near Rhosessmor, was reopened last week after restoration and refurbishing. The structural repairs were executed by Mr. Alfred Lloyd, contractor, Flint, and the internal decorations by Mr. Foulkes, Mold, all the details of the work having been designed and superintended by Mr. Douglas, architect, Chester. The committee also provided new seats for the chancel and nave, which were supplied by Mr. R. Edwards, contractor, Mold.

Lord Crewe unveiled, on Monday, and formally presented to the town of Sandbach a fountain, which he had caused to be built at a cost of £350. The fountain, which has been erected in the centre of the town and is raised on steps of Yorkshire stone, has a pedestal of marble for the centre basin, and a fountain jet surrounded by four basins. The structure is circular in plan, is in the Jacobean style, and has carved in it the coat of arms of the Crewe family. The fountain was designed by Mr. Bowyer, architect, of Nantwich, and the work has been carried out by Mr. John Stringer, builder, Sandbach.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 832, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.). To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of eight words, the first line counting as two the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and SIXPENCE for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL, XLI, XLII, XLIII, XLIV, XLV, XLVI, XLVII, XLVIII, XLIX, L, LI, LII, LIV, LVIII, LIX, LX, LXI, and LXII may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—G. M. and Co.—Ralph.—A. S. R.—M. T.—Plantagenet.—R. and B. G. Co.—T. (Newbury).

Correspondence.

EAST LANGDON CHURCH.

To the Editor of the BUILDING NEWS.

SIR,—I have read, on my return to town, your interesting note with respect to the two ancient windows which we discovered at East Langdon Church during the recent reparation which I have had carried out. Their form is not different from what is usually classed as Norman work—a round-headed narrow light deeply splayed inside—and there is nothing distinctive of Saxon date in this respect; but their jambs appeared to be formed of rough flints, as well as they could be examined, and not of quoins, as might be expected, since all other Norman portions of the church have them, and, in addition, one of them was found to be cut through by an Early Norman arcade. It had been a south window of an aisleless nave, certainly of older date than the added Norman aisle. This arcade, by the way, was swept away at the beginning of this century, and one of our works has been to replace it. The windows, it may be just possible, belonged to a Norman church still earlier than the arcade, but the most probable belief is that they are really of Saxon date. It may be remembered that windows of similar form have been found under similar circumstances, cut through by Early Norman work, at Avebury, in Wilts, and at Iwer, in Bucks, and a Saxon date has been pretty generally assigned to them.

Your remarks with regard to Saxon work in Kent are of interest, and your readers who may care to search will find a good deal of Saxon work in small detached portions, especially in the churches of East Kent, but only plain walling, as at Swancombe, which you refer to, with very little of the usual features of Saxon work, will be

met with, and mostly of materials taken from Ancient Roman buildings. But at Whitwell Church, close to East Langdon, will be found the most complete specimen of Saxon work in Kent, known to me, and which I believe to be of very Early Saxon work. It is a plain building with nave and a small square chancel, with a continuous north aisle. The walls are lofty for the width, the quoins are rough flints, and they remain at almost all the angles. There is a blocked west door of rude flint-work, a stone window in the gable, and a south window with double splay. The chancel arch is much out of shape, and it is of the same early date as the church.—I am, &c., E. P. LOFTUS BROCK.

BRITISH LIBRARY PLANS FOR EXHIBITION AT CHICAGO.

SIR,—I have been requested by the Chairman of the Library Architecture Committee of the Chicago Exhibition to form a collection of British library plans, to be shown in conjunction with a large exhibition of library appliances in 1893, and I take the liberty of inviting contributions from architects who have designed library buildings in this country. The exhibit of plans is intended to be as practical as possible, and for this reason only floor-plans, showing existing arrangements of shelving, tables, counters, racks, &c., are desired. It is therefore suggested that floor-plans, drawn to a $\frac{1}{4}$ in. scale, be sent, and that only the part of the library used for work be shown. This may, however, include museums or art schools where worked along with the library. Photographs or drawings of elevations may also be sent, if thought necessary; and any point which may be considered new or uncommon in regard to construction or arrangement might fitly be emphasised. It is intended to publish a report on the library plans represented at the exhibition, and the hope is entertained that the results of such a great international collection may be preserved in a manner likely to prove of the utmost possible use in the future. All plans proposed to be shown should reach me not later than Christmas next, and I shall arrange to have them carefully packed for free transmission to Chicago. Any further information will gladly be given by me at the under-mentioned address.—I am, &c., JAMES D. BROWN, Librarian. Clerkenwell Public Library, London, E.C.

[It would be well to arrange, if possible, for a short exhibition of the collection here in London before they go to Chicago.—Ed. "B.N."]

LAND SURVEYING.

SIR,—This time it is "Northman" who has seized on a slip in my reading off the diagram in my last letter. Of course, $EF - Ef =$ about $\frac{2}{3}(MF - Mf)$, not $YA - Ya$. $EF - Ef =$ about $\frac{2}{3}(YA - Ya)$. The diagram was not an entirely new case; it was intended to represent the lower half of Fig. 5. The usual way to calculate the amount of alteration of the length of one object whose length depends on another object whose length varies is to take the alteration when motion is just beginning, in which case Mf is (within the limit) parallel to Ya . Perhaps it will be better to take the exact figures given in "Northman's" letter of July 15th. BA is measured 1,530 links, instead of 1,570 links, a difference of 40 links in FA . The check line YA shows a difference of 25 links, while the check-line given in Fig. 5, EF , will show a difference of 7 links. I have already said that I consider this to be ample to show that an error existed, and that taking the line to the point F saved work. I am supported in the view that a cross line such as EF is sufficient check on a triangle by Messrs. Merrett and Uaill and Baker.

I did not give any exact dimensions or "proof" of the check of DB by AF in Fig. 4, as the matter seemed obvious; however, if DB is chained 40 links out, AF will show a difference of 22 links. I have taken the scale of Fig. 5 at 5 chains to an inch.—I am, &c., Gravesend, Sept. 20th. G. W. COBHAM.

DURHAM COLLEGE OF SCIENCE.

SIR,—My attention has been called to a notice of this building in your impression of the 12th ult. I am sure you will allow me to make a slight correction in the description—viz., the drawings for the continuation of these buildings were prepared by the late Mr. Johnson and myself as joint architects, and since the death of Mr. Johnson, a few months ago, the work has been entirely in my hands.—I am, &c., FRANK W. RICH. 5, Eldon-square, Newcastle-on-Tyne, Sept. 15.

Intercommunication.

QUESTIONS.

[10857].—Testing Drains.—Will some reader kindly give me information as to the best way to test old drains?—SWEET GAS.

[10858].—Tar Pavements.—Would any of your correspondents kindly give me the best method of forming the tar pavements in the playgrounds of large School Board schools? I find there is considerable diversity of opinion as to whether the material should be used fresh, or turned over a certain number of times before use. Any information which may either alter or confirm my present views upon the matter, would greatly oblige, and, in order to save time, might I ask for a reply as below, as well as through the columns of the BUILDING NEWS?—J. M. BOTTOMLEY, Architect, Middlesbrough.

[10859].—Hopton Wood Stone.—Can any reader oblige me with his experience of Hopton Wood stone for outside use, monumental or other, in respect to weathering qualities?—W. R.

CHIPS.

The foundation-stone of a new Roman Catholic church which is being erected on land near High Park-road, Smethwick, was laid by Bishop Ilsey, of Birmingham, on the 16th inst. The church will accommodate between 300 and 400 persons.

The new additions to the workhouse, Great Yarmouth, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates, the same being supplied by Mr. E. H. Shorland, of Manchester.

The council of the Royal Scottish Academy have resolved to revert to the old date for their annual exhibitions. The next exhibition of the Royal Scottish Academy will be held, not at Christmas as last year, but in the month of February next.

The erection of a tower and porch to complete SS. Mary and John, Cowley-road, Oxford, has been begun. The architect is Mr. Mardon Mowbray, of Oxford. An anonymous donor has given £2,000 towards the cost of the work.

The first sod of the new Roman Catholic College at Blairs, Aberdeen, was recently cut by Archbishop Macdonald. It will consist of three sides of a quadrangle, and the buildings will be entirely faced with local granite. Messrs. Ellis and Wilson, of Aberdeen, are the architects, and the outlay will be £20,000.

The reformatory at Kingswood, near Bristol, was reopened by Lord Norton on the 14th inst. after having been entirely reconstructed from plans by Mr. Hirst, of Bristol.

The whole of the carvings of the Bishop's throne in Peterborough Cathedral has now been completed and the figures placed in position. At the sides of the seat are representations of St. Peter and St. Paul. On the back board are symbolical representations of temperance, wisdom, fortitude, and justice.

The foundation stones of a new Sunday-school at Potter's-green were laid last week. The school, which will cost about £320, and accommodate 180 children, will be 38ft. by 24ft. The builders are Messrs. Kelley and Son, of Foleshill.

The north-easterly extension of the Leeds Railway will be commenced next month. The contract for the tunnel from Wellington Station to Marsh-lane has been let for £150,000.

An ice factory has been built in Dover-road, Folkestone, and has been started this week. Mr. Joseph Gardner was the architect, and Messrs. Petts and Son, also of Folkestone, were the contractors.

The Heatherdene convalescent home for children in Wetherby-lane, Harrogate, was opened on the 15th inst. It commemorates the fatal accident of June 16, 1886, at the Victoria Hall, Sunderland, and has been built from plans by Mr. John Eltrington, of Sunderland.

A new sea wall is about to be built at Teignmouth at a cost of about £1,250. Mr. Marcus Bridgman, of Torquay, is the contractor.

The Bristol Town Council held a sitting on Tuesday to discuss the proposal of the Docks Board to construct new docks at Avonmouth, together with a landing pier, to admit of Atlantic liners reaching the port at any state of the tide, and a scheme for a railway along the quays, the whole to cost about £1,065,000. Decision was postponed for a week.

The widow of the late Mr. John Clement Mead, architect, died on Saturday at her son's residence, Balcombe Rectory, having reached the advanced age of 97 years.

Among the adjudications in bankruptcy in Tuesday's *London Gazette*, the name appears of W. Macie Leir Seaman, of Victoria-street, Westminster, architect.

The rich screens in the parish church of South Pool, Devon, have just been restored by Messrs. Harry Hems and Sons, of Exeter.

Legal.

WHAT IS A "BUILDING"?

THIS is a question that still frequently comes up for decision in the Courts under the clause in the Building Act of 1855. Perhaps the question should rather be put as: What ought to be a building?—i.e., what sort of structure ought to be built up of walls of brick or stone with a slate or tile roof and proper foundations, instead of being put together with timber? The last case of the kind was certainly a bold attempt to evade the statute, and it is satisfactory to note that the district surveyor succeeded in his summons to the North London Police-court. The structure in dispute was a large erection, part shop and part timber stage, near Dalston Junction. The defendant's case was that, being merely a timber stage, it could not be a "building" within the Act. But from the evidence it appeared that the structure is 17ft. wide, 42ft. long, and 32ft. high. It stands upon timbers for a foundation, and has revolving shutters at the lower portion, and in these are retailed, besides lengths of timber, various wooden manufactured goods, such as step ladders, cornice poles, meat safes, &c.

The magistrate went into the facts, and pointed out that each case must be decided upon its merits. He was not going to hold that all timber stages were buildings. But this was a good deal more than a timber stage, for it was permanently used as a shop, and even had revolving shutters in front for that purpose. It is true the sides of the structure were left open, but that was really done for the convenience of its owner, and did not in the least degree alter the fact that the structure in its lower portion was used and occupied as a shop, and that permanently. More than this, the structure was in the High-street, Kingsland, and so it abutted upon houses and shops in which many people resided. So the order was made that the requirements of the district surveyor be complied with, and thus the ingenious argument that this wooden stage and shop over 30ft. high did not come within the Act as a building has, so far, failed. It is obvious that an exemption of this kind can never have been intended if the Act is to be construed in any reasonable way for the protection of adjoining owners and occupiers.

FRED WETHERFIELD, Solicitor.
1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

CONSIDERATION.—BUILDING.—ARCHITECT'S AGREEMENT.—The whole question is one of fact whether, and to what extent, the original agreement or undertaking was added to by a new and verbal agreement made since. If it can be shown by A. that, as regards the extras and extra charges, B. made such a fresh agreement by, in fact, adding to the old one, this could be gone into in an action for the balance owing.

APPEAL.—LAND.—AGENT.—COMMISSION.—This commission was not really earned until the purchase was completed. There has been no completion. You have been paid part of your commission out of the deposit, and are, so far, fortunate. But I cannot see any legal ground upon which it is possible to claim anything further.

FRONTAGE.—PARTY-WALL.—ROAD.—1. Yes, such an order can be made if the case comes within Section 7 of the Metropolitan Building Act Amendment Act, 1878, which consult. 2. The Act says as to party-walls that the building owner must give the adjoining owner "at the least three months' previous notice," and there is nothing to provide that the work must be begun immediately upon the expiration of that notice or at any special time thereafter.

Lord Lathom has consented to lay the foundation-stone of the Cross Doaf and Dumb School for North and East Lancashire, at Blackburn, on Saturday, October 1, with Masonic honours.

During the past week two memorial windows have been placed in the north aisle of St. Mary's Church, Lichfield. The first window represents the Adoration, and the second the Annunciation. Both are the work of Mr. C. E. Kemp, of London.

The parish church of St. John the Evangelist, of Hipswell, in the North Riding, which was rebuilt in 1811, was reopened on Wednesday week after restoration from plans by Mr. C. Hodgson Fowler, F.S.A., of Durham. The building has been reroofed, the walls repointed, two new windows opened out, new stone terminal crosses erected, and the chancel has been rebuilt to a larger scale. Mr. H. Harwood, of Mansfield, near Darlington, was the contractor.

LEGAL INTELLIGENCE.

DAMAGES FOR EXTRAORDINARY TRAFFIC.—On Saturday, at the Preston County Police Court, Messrs. John Watt and John Wilson, of Glasgow, contractors for the Elston portion of the Thirlmere water scheme of the Manchester Corporation, were summoned under the Highway and Locomotives Act by the authorities of Elston for £86, alleged damage to the roads in that township by extraordinary traffic. Counsel for plaintiffs stated that the average yearly cost of repairing the length of road referred to had been £11 18s.; but in 1891, after the work commenced, the cost had increased to £44 12s. 6d., and so far as the present year had gone £65 6s. 5d. had already been expended. The sum claimed represented the difference between the average mentioned and the increased cost, and the highway rate had been increased from 2d. to 1s.—Mr. W. Dagger, the highway surveyor, supported the case, and Mr. B. Sykes said the claim was at the rate of 3d. a running yard for 1891 and 4d. for 1892, but it would cost fully 1s. a yard. The Bench ordered the payment of £80 and costs.

PENALTY OF DEPARTING FROM THE SPECIFICATION.—At the Chester County Court, on the 15th inst., before Sir Horatio Lloyd, an action was brought by John Jones, joiner and builder, against William Cooper, joiner, for £35 11s. 4d., balance of account owing in respect of two houses built for £410 with certain extras. Defendant lodged a counter-claim for damages in respect of loss sustained through plaintiff not keeping within the terms of the contract. The defendant admitted liability to pay a portion of the balance, but stated that the building had not been erected according to contract. His Honour, in giving judgment, said that it was clear that plaintiff had omitted to put under all the walls a foundation of concrete 2ft. thick, as he had agreed to do under the contract. The amount due to defendant on the counter-claim would exceed that on the claim, therefore he should give judgment on the claim for the defendant, the plaintiff by his conduct in departing from the specification having absolutely precluded himself from any right to claim.

A SWINDLER OF TIMEKEEPERS.—In August last a man named Humphreys was convicted at the Central Criminal Court, before Mr. Commissioner Kerr, for obtaining money by false pretences, and his lordship then expressed the belief that the accused had been the dupe of an individual named George Wilson. That man was subsequently apprehended, and he pleaded guilty on Wednesday week to an indictment charging him with having obtained two sums of £250 with intent to defraud. It was explained that the prisoner had advertised for timekeepers, representing himself as a builder, and the applicants were asked to deposit as security £250. In two cases this amount was obtained, and in other instances smaller deposits were given. The applicants, having made the required deposit, discovered that the representations of the prisoner were false, and that there was no *bona fide* employment, but they failed, however, to recover their money. The deception was a cruel one, because the victims in each case had parted with the savings of a lifetime. For the defence it was urged that the building operations in which the accused was engaged would have been carried out but for the fact that a mortgage had been foreclosed, but counsel for the prosecution declared that Wilson had been connected with frauds of the same description for a number of years. The Commissioner, remarking that the prisoner's conduct had been heartless, sentenced him to three years' penal servitude.

TOLLY V. BLACK.—On Tuesday, the 20th instant, at Greenwich Police-court, Mr. Kennedy gave his decision on this case. On the first point, as to whether the premises were one building or two buildings, Mr. Kennedy decided that they were two buildings, and made an order for the erection of a party wall between them. On the second point, as to whether the upper portion of the wall between Nos. 24 and 26 was a party-wall or external wall, it was decided that it was an external wall, and no order was made thereon.

IN RE A. FOSTER, OF EAST GRINSTEAD.—A statement of the affairs of Alfred Foster, builder and contractor, of East Grinstead, has been issued. The debtor obtained his discharge from a previous bankruptcy in 1884, and his gross liabilities are now given as £24,350. The debtor's estimated liabilities are £16,674, and the assets £1,908, leaving a deficiency of £11,766. At the date of the receiving order the debtor had had over-drafts from a bank to the amount of £15,473 14s.

IN RE J. W. HOBBS AND CO.—An application was made to Mr. Justice Barnes on Wednesday by Mr. Marten, Q.C., on behalf of creditors that this firm of builders should be wound up. Mr. John Chester applied on behalf of the American Elevator Company, who had also lodged a petition for the carriage of the order. He said that his clients' claim was for £32,000, which was secured by mortgages. The builders were the builders of Whitehall-court and of the large flats recently built near the French

Embassy, and called Hyde Park-court. Mr. Ford supported the petition on behalf of the Kensington Electric Lighting Company, who had arranged to light the buildings. Mr. Brodie Cooper and Mr. Eldridge also appeared. A winding-up order was made.

WATER SUPPLY AND SANITARY MATTERS.

CARDIFF.—The works for the better supply of water to Cardiff were completed by the admission of water to the town from the Cantrefr Reservoir on Tuesday week. The corporation acquired the undertaking of the Cardiff Waterworks Company in 1878, and in 1881 instructed Mr. J. A. B. Williams to report on every source of water supply available for Cardiff. Mr. Williams recommended the extension of the Ely pumping station as an immediate means of obtaining an increased supply; the construction of a storage reservoir at Llanishen, adjoining the Llysane reservoir, together with new filter bed and a covered service reservoir—all to form part of a future gravitation scheme from the Taff Vawr Valley; and that application be made to Parliament for powers to take the waters of the Taff Vawr river and its tributaries near the Beacons in Breconshire, for storage in large reservoirs, with an aqueduct to Cardiff. The late Mr. J. F. Bateman reported in confirmation of Mr. Williams' recommendation in favour of the Taff Vawr source. An Act was obtained in August, 1884, for the following works: Three large storage reservoirs, with a total capacity of 1,220,000,000 gallons; three balancing reservoirs at Cefn, Blackbrook, and Rhubina respectively; also a high-level service reservoir and set of filter beds at Rhubina for the future supply, by gravitation, of Penarth, Llandaff, Whitchurch, Maundy, and Penylan; an aqueduct connecting the different reservoirs together, and passing down the valley of the Taff to the two storage reservoirs at Llanishen and Llysane, four miles north-east of Cardiff. The length of this aqueduct is 32 miles. The area of gathering ground above the lowest reservoir of the series is 10,400 acres, and of this the "upper portion" to the foot of No. 2, or Cantrefr Reservoir, contains 4,000 acres of mountain pasture. This gathering ground stands at an elevation of 1,080ft. above sea-level at the embankment of Cantrefr Reservoir, and it rises to a height of nearly 3,000ft. at the Brecon Beacons. The first portion of the works, now completed, comprises the storage reservoir, called Cantrefr Reservoir; the balancing reservoirs of Cefn, Blackbrook, and Rhubina; also the high-level service reservoir and two filter beds for the future high-level service by gravitation of the suburban districts above the reach of the ordinary supply of Cardiff; the aqueduct, or conduit, from Cantrefr Reservoir, passing through the balancing reservoirs, and terminating in the storage reservoirs of Llanishen and Llysane, near Cardiff. The aqueduct was commenced in October, 1885, and completed in September, 1888. The balancing reservoirs, together with the high-level service reservoir and filters, were commenced in December, 1887, and completed in November, 1888. The Cantrefr Reservoir was commenced in March, 1886, and is now just completed, the time occupied in its construction being 6½ years.

DORKING SEWERAGE.—A section of this work, under Mr. Rapley, surveyor to the rural sanitary authority, has recently been completed. The pipes had to be laid under very unfavourable conditions in waterlogged soil at a depth of 13ft., the water rising in places 9ft. above the pipes. Doulton's patent self-adjusting joint, which has proved of great value under such circumstances, was adopted, and the sewer on completion was found to be perfectly watertight.

EASTWOOD AND GREASLEY SEWERAGE.—In December last the Basford rural sanitary authority sanctioned the appointment of a local committee to consider the best means for the disposal of the sewage of Eastwood and Greasley, and they decided that Mr. Herbert Walker and Mr. W. H. Radford, civil engineers, both of Nottingham, should be invited to submit plans, and the committee to decide which was the most suitable. These plans were submitted last March, and after an exhaustive inquiry into the merits of both schemes, the committee recommended that Mr. Herbert Walker be appointed the engineer to carry out the proposed works. Plans will be submitted for approval by the Local Government Board in due course.

THE SEWAGE QUESTION IN THE WEST RIDING.—The Pontefract Rural Sanitary Authority in March last received a scheme for the drainage and sewage treatment of Burton Salmon—an entirely agricultural township—at a cost of £1,500. This scheme, which, small as it is, involves a pumping lift of some 10ft. or 12ft., has been accepted by the township. In May a scheme for the drainage of Brotherton township, at a cost of £2,700, was received, which also involved pumping; while on Saturday, the 10th inst., three alternative schemes were submitted for the drainage of Glasshoughton

township, at a cost varying from £3,000 to £4,000. Two of these schemes are for combining respectively with the adjacent districts of Castleford and Whitwood, by discharging the bulk of the sewage into their respective sewer systems at a fixed charge per house, and the third is for dealing with the bulk of the sewage within and by the township itself. This self-contained scheme was recommended by the authority's engineer, Mr. Malcom Paterson, M.Inst.C.E., of Bradford, as by far the most efficient and economical. In this case, three alternative schemes are by gravitation only, so far as the township itself is concerned; but the Castleford system, which also was designed in 1875 by Mr. Paterson, involves a lift of no less than 60ft. Incidentally, in the engineer's report, it was mentioned that during the past year alone the population had increased 18 per cent., and that this was entirely due to the operation of the newly-completed water supply, thus showing how the supply of vital needs influences population. In all the above schemes it is proposed to treat the sewage on land, which is undoubtedly the best resource in rural districts.

STAINED GLASS.

LARGS, N.B.—Messrs. Stephen Adam and Co., Glasgow, have just completed the erection of two stained-glass memorial windows in the transept of the new United Presbyterian Church at Largs, one representing the angel appearing to Cornelius, and the other taken from Proverbs xxxi., "She stretcheth forth her hand to the needy." The other windows in the church, to be erected by Messrs. Stephen Adam and Co., will illustrate "David playing before Saul," "Christ, Martha, and Mary," and two sketches for another window, representing Boaz and Ruth, have just been finished.

STATUES, MEMORIALS, &c.

DURHAM.—A statue of the late Mr. William Crawford, M.P. for Mid-Durham, was unveiled on Saturday outside the Miners' Hall. The commission was executed by Mr. Joseph Whitehead, of the firm of Whitehead and Sons, of Vincent-square, Westminster. The statue is carved in white Sicilian marble; it is 7ft. 6in. in height, and represents Mr. Crawford in a standing posture. His right leg is set forward, with a finger of the right hand in his trousers pocket. His left hand rests on a pedestal, and the head is uncovered. The statue will be mounted on a block of Aberdeen granite. The statue is in immediate proximity to that of Mr. Alexander McDonald.

CHIPS.

Mr. Thomas Ross Salmond, M.Inst.C.E., of Park House, Belfast, for upwards of twenty-one years chief engineer to the Belfast Harbour Commissioners, has now retired from the board's service, but intends to act professionally as a consulting engineer and arbitrator.

The ventilation of the new Hospital Hut, Pembroke Docks, has been carried out by Messrs. Baird, Thomson, and Co., whose improved patent "Ejus" invisible roof ventilator has been used for the extraction of vitiated air.

We are informed that the old-established firm of John Freeman and Sons and the West of England Granite Company have amalgamated, and will in future be known as John Freeman, Sons, and Co., Limited. It is not the intention of the company to offer the shares to the public. The offices of the late firm of John Freeman and Sons, at Penryn, Cornwall, will be the head office of the new company, and the management will be in the hands of Messrs. Freeman and their staff. An office has been opened at 9, Great Queen-street, Westminster, where the company will be represented by Mr. Bernard A. Freeman.

Mr. Forman, civil engineer, of Glasgow, and Mr. M'Rae, solicitor, of Edinburgh, have made an ascent of Ben Nevis, with a view to a survey of the proposed route for a railway to the summit. It is stated that there is a probability that the undertaking will be proceeded with.

The memorial-stone of St. Paul's Church, Walsall, was laid on Monday. The church will be built from plans by Mr. J. L. Pearson, R.A., and will cost about £9,000, towards which £7,000 is in hand. The tower and vestries will be left over for the present.

A chancel screen has just been placed in the church of St. Michael and All Angels at Folkestone. It was designed by Messrs. Bodley and Garner, the architects of the church; and has been carried out by Messrs. Ruttee and Kett, of Cambridge, the cost being about £700. It is carved in oak, with wrought-iron gates, there being on the lattice work small shields, which will be illuminated. Above the screen, within the arch of the roof, is a rood, also elaborately carved, the cross bearing emblems of the Four Evangelists.

Our Office Table.

THE *conversazione* inaugurating the fifty-sixth session of the Architectural Association is now definitely arranged to be held on Friday evening, October 7th, at the Imperial Institute, South Kensington. The President, Mr. H. O. Cresswell, A.R.I.B.A., and the Committee will receive the members at 8 p.m. It has been arranged that the subway from South Kensington Station will be kept open on that evening.

THE detailed report of the burning of the Metropolitan Opera House at New York, which was regarded as a model of fireproof theatre construction, shows that the damage caused was, as usual, greatly exaggerated in the cabled summaries first received. At the time of the outbreak everything appears to have been done to minimise the fire-resisting properties of the building. The iron curtain between the stage and its auditorium had been raised to its full height, and a temporary wooden flooring had been built over the whole auditorium. On these floors and the stage the scenery of the opera house and of two other theatres was being repainted, and the finished canvases were stacked on the flies and wings. It only needed a little carelessness on the part of a scene painter or labourer to convert the place into a furnace, and this was duly provided. Notwithstanding all the negligence displayed, according to the *American Architect* "the fire-resisting portions of the opera house did their work exactly as they were expected to do it, and the fire gave the best demonstration that we have yet had of the soundness of the principles of theatre construction which are now accepted by architects, and which received their first important application in the United States under the skilful direction of Mr. Cady, in the building in question." With the exception of the stage roof and fittings and the decoration of the auditorium the fabric seems to have been little injured.

THE repaving of Holborn, Chapside, Ludgate-hill and other London streets, is certainly a question which the City authorities have been a long time thinking about, but the principal question is whether they have not made up their minds to adapt the pavement to the gradient of the roads. Surely the smooth paving block which answers in the level portions of our streets is not the best adapted for the inclines, where common sense would dictate a grooved block, or if such cannot be used, the old-fashioned granite paving. Ludgate-hill, now that it has been widened, ought to be paved with a block that will both give a foothold to horses struggling up hill, and offer resistance to the traffic coming down hill.

An Exhibition of Modern Paintings has been opened in the Nottingham Museum and Art Gallery. The council of the Royal Academy lend the Chantrey bequest picture, the sensation of the Academy of 1891, "St. Elizabeth of Hungary's Great Act of Renunciation," by Mr. Calderon. Sir J. E. Millais is represented by his "Widow's Mite," lent by the Corporation of Birmingham. Mr. G. F. Watts contributes his portrait of Mr. Walter Crane, recently hung in the New Gallery Exhibition. Mr. La Thangue has sent his "Mission to Seamen," and Mr. Bourdillon is represented by "The Only Survivor." Mr. F. W. W. Topham contributes a large picture entitled "Judas," which has also been seen at Burlington House, as has a landscape by Mr. D. Farquharson of "A Scotch Mountain River Scene."

THE destruction of lead water-pipes by electric action is one of the results of laying on electric currents by the side of water-pipes. A report by Major Cardew, R.E., to the Board of Trade, draws attention to the damage sustained by a lead water-pipe and a gas-meter in proximity to a culvert of an electric supply company. The main of the company was found just above the water-pipe, which had been eaten through twice within a few months. Tests with the galvanometer established the fact that there was a difference of potential of about 6 volts between the iron culvert and the water-pipe, the former being negatively charged as regards the pipe. Water was found in the electric culvert, which had touched the positive main. Some lead-covered wires used as pilot wires had been fused, and the expert stated that he had little doubt that a connection between the negative conductor and the

iron of the culvert was effected by the fused and stripped ends of these pilot wires. The flow of positive electricity from a metal into a damp medium or water generates oxygen at the surface of the metal, which is thereby corroded, and this action destroyed the water-pipes. The gas-pipe encased in bitumen was unaffected.

THE Edinburgh town council will promote next session a Municipal Improvements Bill for carrying out various works involving an estimated cost of upwards of £74,000. The principal improvement consists of the widening of Bristol-street, Salisbury-place, and other thoroughfares by the removal of extensive blocks of buildings, and the construction of a new street in the Fountainbridge district.

THE Architectural Association.—October 1st. Summer Visit to St. Alban's Abbey, St. Michael's Church and Gateway, postponed from September 3. Mr. James Neale, F.S.A., has kindly consented to act as guide. Train 2.5 p.m. from St. Pancras. P.O. for 2s. 6d. to be sent to Mr. Francis Hooper, 14, Sackville-street, W., before Thursday, September 29th.

Trade News.

WAGES MOVEMENTS.

COLNE, LANC.—The plasterers' strike at Colne and Nelson has terminated, the men's wages being advanced from 7d. to 8d. per hour.

LANCASTER.—The joiners' and carpenters' strike at Lancaster, which has lasted nearly 11 weeks, was settled on Friday at a meeting of masters and delegates. The men receive an advance of 3d. per hour, making 7½d., and commence work at seven on Monday mornings instead of six. There are other concessions as to overtime, time and a quarter to be paid after half-past five, and time and a half on Sundays and Bank Holidays. The men asked for 3d. advance.

A permanent Gothic Roman Catholic church accommodating 600 persons was opened at Silver-town, E., last week. Mr. Tasker was the architect.

A new water supply for the village of Berry-narbor, North Devon, has just been completed at the cost of £700, at the sole cost of Mrs. Basset, of Watermouth Castle. A new reservoir has been made, and a main pipe laid down. The excavating, which has been considerable, owing to the hard nature of the rock, has been executed by men on the Watermouth Estate, the reservoir having been built by Mr. Garland, of Barnstable, and the plumbing was done by Mr. F. Steer.

At the last meeting of the Mersey docks and harbour board, a recommendation of the marine committee was adopted to expend a further sum of £10,000 in experiments for the improvement of the port of Liverpool by removing sand from the bar of the Mersey.

The work which has been carried out in connection with the restoration of the ancient church of St. Mary's, Fairford, was dedicated at a special service on Tuesday by the Bishop of Gloucester and Bristol. The restoration, which has cost over £5,400, has been carried out from the plans of Messrs. Waller, diocesan architects, and the re-casing of the roof was intrusted to Mr. James, of Cirencester.

Mr. Hubert Herkomer, R.A., as purchaser for the National Gallery, Melbourne, has written to the trustees of that art institution to the effect that he has bought modern pictures, because he did not like to spend public money on works of doubtful authenticity, and that he knows no more risky venture than collecting Old Masters.

Mr. Frank Wood, C.E., has been recommended by the general works committee of the city council of Wakefield, from among 80 candidates, to the appointment of assistant city surveyor, and to take charge of the sewerage and sewage disposal schemes of that city. Mr. Wood was assistant surveyor to the local board of Walton-next-Liverpool until two years ago, when he was appointed assistant to the borough engineer of Leicester.

Sir Massey Lopes has laid the foundation-stone of a new church, which is being built at Horrabridge, Devon, at a cost to himself of £2,000, as a memorial to his daughter Louisa, who died suddenly two years ago.

The Dundee Fine Art Exhibition Committee have resolved to hold an exhibition, to be called "Old Dundee," in the coming winter, with the object of illustrating the history and development of the city.

The new branch line from Paddock's Wood Junction to Goudhurst and Cranbrook was opened last week.

DOULTING FREESTONE.
THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLEDITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doultong, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

AYR.—For the construction of the first section of the extension of the esplanade, for the town council:—
 Clarke, W. (accepted) £1,374

BATH.—For the erection of the new municipal buildings, for the city council. Mr. J. M. Brydon, of London, architect:—

Escourt T., Gloucester £27,823 0 0
 Hayward & Wooster, Bath (accepted) 22,253 0 0
 (Ten intermediate tenders received.)

BRIDGNORTH.—For retiling the roof of the Grammar School, for the town council:—
 Bowen, T., Netchworth (accepted).

BRIXTON, S.W.—For shop fitting, 212, Brixton-hill, for Mr. T. Lighton. Mr. M. V. Treleven, Acre-lane, Brixton, architect and surveyor:—

Joiner, painter, &c.:—
 Freight £481 14 9

Braby and Co. 114 6 4

Carter and Co. 59 6 0

Green and Son 61 0 0

BRACKPOOL.—For brickwork in connection with the Blackpool Tower Buildings. Messrs. Maxwell and Tuke, architects:—

Cardwell Bros., Blackpool* £7,832 8 4
 * Accepted.

BROADSTAIRS.—For the erection of a detached house on a piece of land situate off the Rectory-road, Broadstairs, Kent, for Mr. Frank K. Cochran. Mr. William A. Burr, M.S.A., 65, Chancery-lane, W.C., architect:—

Paramor and Son, Margate £1,700 0 0
 Oldrey, London 1,450 0 0
 May, Broadstairs 1,285 0 0
 Martin, Ramsgate 1,199 0 0
 Brown and Son, Margate 1,150 0 0

BURSELM.—For fencing in the Grange recreation ground, for the town council. Mr. Mawson, surveyor:—
 Elsby, R. C. (accepted) £123 0 0

COVENTRY.—For the restoration of the great north window of St. Mary's Hall, for the city council. Mr. Edward Burgess, architect:—
 Grylls, J. T., London (accepted) .. £300 0 0

(Estimated cost of restoration of stonework of window, £329.)

FROME.—For new villa residence, for Mr. W. R. Wheeler. Mr. W. G. Brown, Frome, architect:—

Seward, T. J., Frome £590 0 0
 Hodder and Sons, Frome 545 0 0
 Chislett and Son, Frome (accepted) 502 0 0

FROME.—For new shop front and other alterations at No. 1, The Bridge, Frome, for Mr. Charles Waters. Mr. W. G. Brown, architect:—

Hodder and Sons, Frome £248 0 0
 Seward, F. J., Frome (accepted) ... 215 0 0

HIGHBURY.—For alterations and additions to the Islington Relief Offices, Highbury Mews, N., for the guardians of the poor of the parish of St. Mary, Islington. Mr. William Smith, A.R.I.B.A., 65, Chancery-lane, W.C., architect:—

Bellew £200 5 0
 Whitehead and Co. 180 0 0
 Linfield 170 0 0
 Ward and Lambie 148 0 0
 Ruffell 140 0 0
 Harvey 138 0 0
 Marchant and Hirst 137 7 0
 Langham 137 0 0

ARCHITECTS AND PUPILS.

"THE odd thing about pupils is, that the less they pay the more they expect." So a well-known architect was heard to remark some time ago—and his statement was by no means destitute of foundation. The young man who, in return for a premium of several hundred pounds, "gets the run" of a large office is generally content—at least, while his articleship lasts. If he has paid less than two hundred, he will expect more individual care and notice; while if his premium has been almost nominal he, or his friends for him, will feel ill-used if the principal does not give him a large share of his time and attention. For some people even this is not enough; and parents have been known to expect that an architect, on being intrusted with such a treasure as their boy, should give up looking after his buildings, and sit in the office all day to watch over him. Others are more anxious that their child should never be called upon to do anything menial or derogatory. In an action brought by a man of this sort some years since, the head and front of the principal's offending was the fact that in changing offices he had directed his pupil to carry a small gas-meter across the street.

Moralists tell us that human folly is boundless, and for some of these ridiculous fancies it must certainly be held responsible. If a boy is so weak and silly that he needs incessant watching, he should have been kept at school till he grew wiser. If he is too delicate to touch anything rougher than a sheet of paper, he should have been apprenticed in a fancy-shop, and not thrust into a profession which will require him to pick up bricks and handfuls of sand, and to rub his nice clean clothes against dirty ladders. But many complaints spring from misunderstanding. A pupil does not know, and his friends do not know, exactly what he ought to be doing, or what sort of training he ought to have. They are aware that he must be able to draw, and that he will have to distinguish good materials from bad. But of the infinity of other things which an architect has to learn, they never dream, and when a pupil is kept for any considerable time at these other things, they vaguely suspect that he is being neglected, and is wasting his time.

Sometimes an architect has to teach things that ought to have been taught at school. A lad, supposed to be well educated, cannot, perhaps, write a legible hand; he cannot compose a grammatical letter, or spell it when he has composed it. Perhaps his arithmetic is at fault, and he cannot square up a few simple dimensions, or add up a column of figures. Such things as these should not need to be taught in an office, and yet office training can hardly go far till they are taught. But if a pupil is set to perfect himself in necessary preliminaries of this kind, he feels, naturally enough, that they are not architecture, and that he was not articled to study them. It is quite true; but then he should have studied them before his articleship began. Suppose, however, that he starts fair. The difficulty then is, that in the three or four, or even five, years of his term he can only take up effectually a part of the subjects which he will need to be familiar with. The wisest course, perhaps, would be to make a selection at first: to apply himself thoroughly to the subjects he selects, and to go on with the rest after mastering these. But this is not the plausible course. No matter that the

ordinary term is not half long enough to make the cleverest pupil into an accomplished architect; no matter that diligence in pupils is by no means universal; clever or dull, diligent or idle, they all expect to learn a little of everything. And the principal who does not give them a little of everything must expect to have it said of him, "I was articled to Mr. So-and-So: I was with him so many years; and yet he never taught me a particle of this, and that, and the other."

We are not saying for a moment that no architects are indifferent, and that no pupils have ground for complaint. We are merely pointing out that pupils, and especially their parents, not unfrequently complain through ignorance. They do not know when they are being well treated. Let us see, therefore, what is comprised in a thorough architectural training. First, then, there is drawing, which is acquired rapidly by some and very slowly by others. The sort of drawing that is necessary varies much in the different branches of the profession. The pupils of the shed and factory architect require to rule straight lines neatly, and to draw plain plans to scale. Those of the artistic architect begin where the last-named leaves off, and require a thorough knowledge of detail, as well as great skill in execution. The decorative architect's work needs these last accomplishments, with freehand drawing besides—enough by themselves to occupy a whole articleship, and to form the basis for a special type of practice. Merely geometrical drawing, again, is not enough. Every architect should be able to sketch rapidly in perspective as well as to draw carefully in it, and to do either implies very considerable progress. But suppose drawing fairly mastered—a supposition which the charity that "hopeth all things" may entertain—perhaps about one pupil in a dozen after four years' work. Then comes construction. The rudiments of this will have been picked up in copying drawings and details. But to pursue the subject, to know the best ways of building even simple structures, and to understand why those ways are best, to go on to more complicated cases, to foresee the weaknesses which time will bring out, and to provide against them, to design, to calculate, and to invent new types of structure. This is obviously a sort of training that will be going on for a lifetime. Every pupil should be made familiar with the beginnings of the science, but he will be far beyond the period of pupilage before he is thoroughly at home in it.

The study of materials will naturally go on at the same time with that of construction. With the pupil who lives in a large town, and keeps his eyes open, it will be always going on. Everywhere he will be able to learn, both from old buildings and new ones. In the former he will see what sorts of stone last, and what sorts decay, and he will notice whether the decay arises from bad material, or only from improper bedding. He will mark the shrinkage of joinery, and familiarise himself with the aspect of inferior wood. He will see how sappy edges begin to moulder, and ill-seasoned beams to twist. So in every trade he will be on the look-out for defects that he may guard himself against the causes that lead to them. Where buildings are in progress he will narrowly watch the class of materials that are being supplied; he will form his own opinion as to those that ought to be rejected, and be interested in ascertaining whether or no they are allowed to pass. Where foundations are being dug out he will judge as to their goodness or badness, and see whether proper means are adopted to make them secure. An immense amount of information is in this way accessible to every pupil as he goes along the streets. It does not matter whether the buildings he looks at are, or are not, being executed by the architect to whom

he is articled. If they are, an idle pupil may go about them day after day, and month after month, and be none the wiser for his wanderings; and if they are not, a great deal of the training they can supply is open to everybody who cares to look and consider. There is no special magic about the buildings that are being put up from designs made in the pupil's office. If he wants an excuse for not learning, he may make one up out of the fact—should it happen to be a fact—that his principal has few buildings in hand which are near enough to be accessible to him. But in towns like London, and like a hundred smaller ones, it is only an excuse. Materials may be studied in one building as well as in another, and where work is going on, or has gone on, teaching is always going on, too, for those who have ears to hear it.

That architectural training, again, is a very poor one which does not teach the student to think. Some pupils have a tendency to lapse into mere machines. Give them a drawing to copy, and they will copy it admirably. Give them the smallest bit of work that requires thought and at once they are paralysed. Sketch out roughly, for instance, the ground plan of a cottage, and ask them to draw it to scale. A. perhaps will give his mind to it—will try to realise the requirements and to supply them. He may make mistakes, but they will be the mistakes that arise from imperfect knowledge—the mistakes that are natural and excusable to anyone with only two or three years' training. B., on the contrary, either from want of thought or from mistrust in his own abilities, will make mistakes of quite a different kind. A. may be depended on to see that every room has a door and a window, though he may put his doors and windows in places which are not the best. B., on the contrary, is as likely as not to leave out both doors and windows. Sometimes he does this from want of imagination. To him the plan does not stand for a view showing the arrangement of a possible cottage, in which he can fancy himself walking about, and going from one apartment to another. To him it is merely so many lines ruled in, some going lengthwise on the paper and some crosswise. Or perhaps he is so anxious not to put the doors and windows in bad places, that he falls into a state of irresolution, and cannot make up his mind to show them at all. A remedy for this would be for him to make half-a-dozen alternative plans, showing doors and windows in different positions. Out of these he might select the best, and by efforts of this sort he would effect real progress. In one way or another, progress of this sort is indispensable. The very essence of an architect's work is the solving of problem after problem, of puzzle after puzzle. If he is anything, he is a fighter of difficulties, a conqueror of things too hard to be conquered by untrained intelligence: and he cannot begin too soon to strengthen his mental muscles and sinews for the labour of his life. In other words, he cannot begin too soon to plan and to design, and no more valuable training can be given to him than to let him assist in shaping the form and arrangement of some architectural work.

If a pupil has got in him this capacity for dealing with difficulties, sooner or later he is pretty sure to learn all he needs. There is plenty of it: architecture proper, with the endless details of different styles; the planning of the various sorts of buildings he is likely to be intrusted with; the local regulations which he will have to conform to in different parts of the country; the laws and decisions about light and air cases; sanitation, drainage, plumbing, warming, and ventilation—with a list of other things that might stretch out to the crack of doom. Talk of learning them all in three years! Threescore years are far too short; and if it were not that one class

of work falls to one architect's share, and another class to another's, it would be beyond the power of human faculties, in this 19th century, to be an architect at all.

MANY-STORIED BUILDINGS.

THE requirement of height in modern buildings, or the number of stories, apart from sanitary considerations, has not, on the whole, been favourable to that dignified treatment of our architecture which we see in ancient examples. Restricted areas of site have mainly brought about the change to which we draw attention. In nearly all our new streets this element is beginning to assert itself in a manner that cannot be said to exhibit any promise, rather savouring of a multiplication of small and ordinary features. Comparing the work of the generation preceding our own, a largeness of scale is conspicuous in the elevations; the columnar ordonnance was proportioned to the whole or the upper half of the building, as we find in edifices like the Royal Exchange, the Bank of England, St. George's Hall, Liverpool; or, again, in Somerset House, Greenwich Hospital, Burlington House, and a number of other well-known buildings. In the Parliament Houses even, with its numerous subdivisions and elaboration of detail, we have a structure of two main stories. These are, perhaps, exceptional examples of edifices erected on picked sites, yet they serve to illustrate in a somewhat exaggerated manner the contrast between the old and new methods. The piled-up story is a modern invention to be seen in the huge club-houses and hotels in Northumberland-avenue, the Victoria Embankment, at South Kensington, and many other parts of this overgrown metropolis. What it is destined to become we do not know, though we devoutly hope the craze will never reach the proportion it has done in Chicago and other cities of the States, where the "Manhattan" the "Monadnock," the "Title and Trust," and others are buildings that have reached sixteen stories in height. To say nothing of this fashion of piling people in huge cases of layers or floors, we can estimate the effect of this vertical repetition of features. Where, we ask, is the architecture in this huge structure of piled-up stories? Such a building has lost all claim to the title of being architecturally designed, or to be mentioned in the same breath with any of the single-storied or triple-storied structures of the Classical Revival. It is no longer a piece of architecture, but a collection of stories comparable to a chest of drawers or a case of pigeon-holes—a vertical repeat of one unit. No design runs through the composition, as in the case of a façade with a single order, divided into parts as a projecting centre and wings. Let us imagine two hypothetical treatments—one of an architecturally-divided building, and the other of the multiplication of stories. Let us take, as an instance of the first, a building of, say, 100ft. frontage and 50ft. in height, divided vertically into three stories, the lower one a bold basement, a principal floor of large windows, and a lower upper story. The two upper stories may form part of an ordonnance of a single order of columns, as we see on the façade of the Banqueting Hall, Whitehall, and in that of Somerset House, both examples of the Palladian-Italian; we have in such a division of fenestration a dignified front. The façades of the Reform and Travellers' Clubhouses in Pall Mall afford the same three-fold division of stories, only without columns, considered by all competent authorities excellent examples of the Astylar-Italian. Now add another story or two, and the whole scale is reduced, and the dignity and repose of the elevation is lost. It makes no difference if we make the block higher; the

architectural unity is destroyed. We may improve the façade by breaking it into a centre and end wings, by pediments or pavilion roofs, but the composition still lacks that oneness and connection which we have in the first case. The crowded window front is the *crux* of modern architecture; how to bring it into any order or arrangement of parts is one of the chief difficulties in the design of buildings like hotels, blocks of industrial dwellings, and warehouses. Requirements often involve a repetition of stories and windows of like size and proportion. A modern hotel or block of dwellings in flats calls for stories of similar height, and the windows are necessarily repeated on each floor. As quite a recent instance, we may mention the designs for the Manchester Technical School, which have just been exhibited, many of which represent the main fronts filled by six stories of windows, perfectly flat, without any projections or divisions. This number of floors had to be provided to accommodate the several departments and the competitors within the space of ground. Under these conditions it was impossible to adopt the more limited number of stories, and many of the designs represent, as a consequence, lofty façades to the principal streets filled with windows of a commonplace kind. The meagreness of many of the elevations submitted is to be attributed to this cause. The many-storied structure for technical schools, industrial dwellings, and other similar purposes, opens up a new problem in architecture. How they can be made agreeable to the eye is a point for the architect to decide. The monstrous American erections to which we have referred display the first attempts to master the problem of putting as many stories as possible under one roof. The introduction of a massive rusticated basement or lower story of granite with wide semicircular arched entrance, with a variation in the vertical lines of window openings, are features of merit. A low basement story of ordinary height would be crushed in appearance under 12 or 14 upper stories above it—it would look as if it had sunk into the ground. Exceptionally bold and massive treatments have been shown in the "Auditorium Building," Chicago, one of the largest and highest buildings of the kind in America. The third lower stories are of rough granite, with wide intervening piers between the windows, and above this the fenestration is comprised under a lofty arcade of recessed arches embracing four stories. The angles are massive and wide, and above the windows are arranged in pairs of two stories. The Title and Trust Company's building has three lower main divisions or stories of granite. The windows are placed in pairs above, and the upper story forms an arched attic above a bold cornice forming a balcony. In other buildings of this class wide piers ascend between windows, arranged in pairs or triplets. All these attempts to introduce variety and unity in the fronts are worth study.

We may in conclusion draw attention to two or three modes of dealing with fronts of many stories. The worst is a large flat wall pierced by windows, evenly spaced, and of similar size. The eye vainly strives to find order and rest; to detect design is impossible, for there is none. A second, and almost as unsatisfactory, is to divide each story horizontally by cornices or string-courses. The next mode is to pair the windows, to bring them together in vertical rows with wide intervening wall spaces, a plan that at once introduces order. If the openings themselves are varied in height and shape, an additional element of interest is given. Better still is the grouping of windows by placing them in twos or threes; and this may take the form of lateral or side-by-side lights, and those in tiers under one arch. Each of these methods may be illustrated by examples.

The last mentioned, made of grouping, may be noticed in the adopted design for the Municipal Buildings, Oxford, illustrated by us in July, and in the just-selected design for the Manchester Technical School we published last week. Here it will be noticed the windows are pleasingly grouped in twos and threes on the Sackville street front, superimposed and slightly projecting. Other modes of producing variety are open, as, for instance, recessing, advancing, alternating the series, &c. The horizontal division in stories is often overdone by string-courses, &c., the effect of which is to produce a piled-up or chest-of-drawers-like appearance; but the vertical grouping, or what we may term the "pier and window" arrangement, has grown into favour with the revival of Italian, Flemish, and other varieties of Renaissance. A well-marked basement story and cornice below the upper tier of windows considerably break up and relieve the façade of many stories, and it is a marvel, too, what grouping and gathering up the windows into vertical rows does. The same number of distributed single windows would produce an effect at once overcrowded and confusing. Our prodigious blocks of residential flats, monster hotels, and warehouses, which we find in every West-end suburb, Victoria-street, Knightsbridge, Kensington, Soho, and other parts, still encumber the ground with their senseless disregard of those principles of distributing their many stories and windows.

SEASIDE DWELLINGS.

THE seaside dwelling is a typical structure of its kind, in which a small frontage with a display of bay windows and balconies leads one to expect superior accommodation to that afforded in the ordinary town house; but the expectation is not realised. The value of sea-frontage has restricted one important dimension, which is felt as much in the streets at right angles to the front, where the attempt has evidently been to get as many houses as possible in the short distance between one street and another. We find this to be the rule at Brighton, Eastbourne, Worthing, and, in fact, all places where the sea-frontage is the great consideration. With such a condition we can expect little but cramped passages and stairs, small rooms, and deficient office accommodation. That many of these houses were built as private dwelling-houses at a time when the town was just growing into popular favour may explain the insufficient attention paid to planning. As boarding houses or apartments they were not intended; the system of *en suite* apartments or "flats" had not become acclimatised when half these dwellings were erected. The migrating Londoner was scarcely so well known. He now demands superior accommodation, and desires to have all his rooms, if possible, on one floor. It is extraordinary that with a regular "season" of residence by the seaside, so little has been done, except in one or two well-known resorts, to adapt the old-fashioned house to the new requirements. In many of the houses even the *en suite* arrangement has not been introduced, the separate landing entrance to each room remains, with all the attendant inconvenience arising from different families occupying the same floor. In many houses situated in the main front and side streets of Brighton and Worthing this sort of accommodation has to be endured. In a few houses a doorway has been made between the front and back rooms, thus converting them into distinct flats; but a great deal more is wanted. The conveniences are, perhaps, downstairs, also small and cramped, or some kind of improvised projection has been made at each landing for the purpose. Externally the bay window is a recognised feature in most seaside towns; it is sometimes carried up to

the upper floor, and in the side or off-streets it becomes a boon, as it allows a view to be had of the sea from every front room. In the larger houses, facing the sea, the bay is often combined with a balcony, which forms a sort of connecting outside corridor between the bays. In many of the new residences at West Brighton this arrangement is quite common. Much may be done nevertheless to vary the design by making bayed projections, and by a better class of ironwork than that usually met with, which is exceedingly commonplace and weak-looking. The loggia is seldom found as an integral part of the design. Even in the "Grand" and Métropole Hotels we have stereotyped forms of balconies that break up the façades into horizontal parts without vertical supports. The old-fashioned stucco and paint, too, appear to hold supremacy in many of these towns. Along the Brighton front two or three innovations have been made, one by a terrace of large houses at the West-end, which serve to break agreeably the long line of white painted stucco. But the air of 18th-century respectability and correctness still lingers over George IV.'s marine residence, and the palatial squares and crescents seem to repel the less Classical and fashionable taste of brick Renaissance, with its angle turrets and gables. The experiment, at least, can hardly be said to have succeeded along the sea front, where there is such a predominance of the severer lines; certainly the freer and picturesque varieties make the contrast too violent. The bayed or circular-shaped front seen in some towns of this class, notably at Brighton, is a bold and welcome change on the straight front, as the lines of fenestration become varied, and the windows at the sides of the curve enable a wide prospect to be enjoyed. More might be made of this kind of elevation and that with splayed sides; but the builders of houses in these resorts are content to follow the traditional type of dwelling, without looking for better models. The building of seaside towns is purely a commercial or speculative concern, and architectural designs find little favour among local builders. The few good houses one sees are by London men, who, however, are ignorant of the essential requirements of seaside dwellings, and have made such glaring mistakes as to aspect, and to details like weather-proof casements, that the local builder profits by their deficiencies, and with exulting scorn points to the London architect's blunders.

THEATRES.—IX.

By ERNEST A. E. WOODROW, A.R.I.B.A.

SO far it has been my duty to explain the position of a theatre, its division, and arrangements of the interior of the auditorium. My next task is to endeavour to describe the means of entrance and exit to the street for each part of the house.

Every section of the auditorium should have at least two exits leading directly into the street, one or both of which exits being used as the entrance. Were it possible, it would be a great benefit to the public if every exit were also used as an entrance; for it is found that an audience will invariably depart by the way it came in to a theatre. Were the people, therefore, admitted by two separate ways to each division of the auditorium, there would, of a certainty, be insured a nightly usage of all the exits provided. A theatre may have as many exits in proportion to the number of people accommodated therein, and yet be sadly deficient of the necessary means of escape in the case of alarm or panic. Exits that are not known to, and cannot be easily found by, the audience are of very little service indeed; it is money thrown away to construct them. The way of escape should be so placed as to be most readily accessible by the audience; it should not be long or tortuous, and it should always lead directly into a public street, and not be met by any other stream on the way out. An exit must be "separate" its entire

length. I must at once, before going deeper into the question, refer to the London County Council's tenth regulation on entrances and exits, which reads as follows:—

"Two separate exits, not leading into the same thoroughfare or way, shall be provided to every tier or floor of such premises.

"If any tier or floor shall be divided into two parts, two separate exits, not leading into the same thoroughfare or way, shall be provided to each of such parts.

"Such exits shall be arranged so as to afford a ready means of egress from both sides of each tier or floor, and shall lead directly into a thoroughfare or way."

Now the last part of this regulation clearly calls for a symmetrical plan, with exits in corresponding positions on each side of the auditorium and on every tier, so as to afford a ready means of egress from both sides of each tier. Where that is carried out, anyone entering on the right, and seeing a similar door on the left marked "Exit," would naturally feel that they could find a way out, corresponding with the way in by which they entered. This point is briefly touched upon in Chapter II. of this series of articles (page 140, BUILDING NEWS of July 29, 1892); but its importance is so great in my mind I cannot refrain upon further notice of it, especially considering the demand contained in the rules which govern the London architect in preparing his plans. As I have elsewhere observed, it is clearly the duty of the architect to design his building so as to reduce the chances of panic to a minimum, and one of the chief provisions to this end is short and unobstructed exits. Everything in and about a theatre should tend to make the audience have confidence in their own security, and give them a feeling that, should anything happen, they would be able to help themselves without causing injury to others. Where people feel, or think, they are safe, the chances of danger are small. Simplicity in the plan, and uniformity in the two sides of the house, tend towards the solution of the difficulty. Thus, where there is a pit entrance on the one side, a pit exit should be found on the other; where there is a gallery staircase on the right, a gallery staircase should be found on the left, and so on for each tier or division of the audience. People—I repeat—as a rule, naturally desire to leave a building by the door by which they enter, and it seems it is only by making the two sides of a theatre alike that the public will find the exits provided. The audience should be taught the way out of a theatre by habit; to speak of "alarm exit," "fire exit," "exit in case of need," is only to encourage nervousness. The suggestions of danger should never be breathed in a building where human beings are packed.

The number of exits required in foreign countries for each tier of the auditorium varies but little from the dual system demanded by the London County Council. Italy, however, requires three exits from the pit, each delivering separately into the street; and in Hamburg, for every two hundred persons for which accommodation is provided, there must be at least one exit, while in Brussels a width of exit of 3ft. 3in. is required for every one hundred persons.

In Austria it is enacted that the exits must be of such a number as to allow the theatre to be emptied in four minutes, and the size of the doors is specified to be at least 4ft. 10in. wide by 9ft. 8in. in height. 1ft. for every seventy persons is the basis for the calculation of exit space adopted in Glasgow; but where separate exits are provided for the different tiers, they must not be less than 4ft. in width. New York requires each exit to be at least 5ft. in the clear, and every theatre accommodating three hundred persons must have two such exits, and when accommodating five hundred persons at least three exits must be provided for every additional hundred, or part of a hundred; above this an increased width of 20in. must be allowed.

The Boston regulations as to exits should not be overlooked. In this city the audience-hall and each compartment, division, and gallery of every theatre must respectively have at least two independent exits; as far apart as may be. Every such exit must have a width of at least 20in. for every hundred persons which the hall, compartment, division, or gallery from which it leads is capable of containing, and no exit may be less than 5ft. wide. Every theatre in Boston must have a frontage as wide as the widest part of the auditorium, including side

passages and lobbies, the whole width and height of which frontage must be on a street or area open to the sky, and at least 30ft. wide opposite the entire frontage. In this frontage there must be at least one exit, in no case less than 5ft. in width, with such greater width as an allowance of 20in. for each one hundred persons which the building may at any time contain, will, in the aggregate, be required. There must also be another independent exit of the same capacity, or independent exits of the same aggregate capacity, to a place open to the sky. This arrangement, I take it, holds good for each "compartment, division, and gallery of such building," as aforesaid.

Sir Eyre M. Shaw sums up this question by saying that "in at least one country on the Continent the rule is that two exits are required to be provided for 300 persons, and three exits for 500, and the principle of making not only the size, but also the number, of exits bear some recognised proportion to the audience is decidedly a good one, and might with advantage be adopted here."

So much detail is apt to become confusing; but the importance placed upon this question by other countries demands our undivided attention, in order that we may the more easily understand the spirit in which the rule of the London County Council, which specially governs the width of the entrances and exits to a theatre, is framed. No. 15 of the regulations enforces that "every staircase, landing, lobby, corridor, or passage intended for the use of not more than 400 persons of the audience shall be formed of fire-resisting materials, and shall not be less than 4ft. 6in. wide; but if communicating with any portion of the house intended for the accommodation of a larger number of the audience than 400 persons, it shall be increased in width by 6in. for every additional 100 persons until a maximum width of 9ft. be obtained." I am personally of opinion that it is not well to increase the width of an exit beyond 6ft., and should the numbers accommodated in any section of the theatre demand a further width of exit, that the number of exits should be increased rather than the width of the existing ones. This is especially the case in corridors and staircases, where, if an excessive width is attained, the people no longer have the support of the walls to prevent them falling and being trodden to death. The actual exit door itself, of course, cannot be too wide. I would rather see three exits of 6ft. each than two exits of 9ft. each.

In the report of the special committee of the Franklin Institute on the prevention of fires in theatres, which is dated April 18th, 1893, a series of rules were presented, the first of which bears directly upon the question of exit, and which I think should receive our special notice. It reads that "all corridors should increase in width from the theatre to the open air." This, of course, requires that the external exit doors should be wider than those by which the audience pass from the auditorium into the corridors, and is a further development of the principle advocated in the last chapter with regard to gangways widening towards the exit.

I mentioned above the desirability of making all the exits serve as entrances, when carrying out the rule of a dual system from all parts. This, however, would, while entailing duplicate entrances to each division of the audience, demand a double set of pay-boxes, money-takers, check-takers, &c., and would so increase the working expenses of the house as to practically forbid its adoption in small theatres. I think the practical remedy is the adoption of the symmetrical plan. In large theatres, such as Drury Lane, where there are two entrances to the pit, one is frequently used as an "early door," where admission can be obtained sooner than at the ordinary entrance, by the payment of a higher price. This is a managerial arrangement which only affects the architect in so far that it is well to provide a pay-box to each entrance, which is also an exit, in order to meet the requirement of a special entrance under such circumstances.

It has been my object, so far as my knowledge has allowed me, to draw the attention of the readers of the BUILDING NEWS, in these articles, to the views of the various authorities upon the individual details which we have had from time to time under review in the preceding chapters. It will be seen from the above that the views which all authorities have with regard to the vastly important question of exit appear to be the

same on principle, and differ only as to degree. I have, however, to consider other opinions before leaving the subject. Sir Eyre M. Shaw says that the external street approaches should invariably be kept free and unobstructed, as they may at any moment be required for a rush of the audience, and such of the inlets as also form the exits should be not less numerous than the internal divisions of the auditorium, according to prices. Each inlet should be easy of entrance at its outside point, well lighted, free from small projections or obstructions likely to cause injury, quite free from steps at any point where a crush is likely to take place, and gradually narrowing to the width of the narrowest internal passages through which the visitors have to reach their seats. The same writer remarks that: "The means of ingress and egress are not at present" [1876 is, I believe, the year in which these remarks were made] "what they ought to be is abundantly shown in many theatres by the practice of having a light piece to play the audience in, and another to play them out, a practice which, as far as can be judged, seems to have arisen solely through the difficulty experienced in filling and clearing the place when there is no panic. Where this is not done a large portion of the audience leave their seats before the conclusion of the performance, to avoid the inconvenience and delay of having to join the crowd in corridors and passages too small for the purpose." Since this was written matters have somewhat changed, and I do not think the custom of playing "curtain raisers" is so universal now; from which it may be perhaps judged, according to this argument, that the ingress and egress to theatres have improved of late years. At any rate, such is the popular belief, which, I think, is well founded, and trust may not be mistaken. My personal knowledge does not lead me to speak fully of provincial theatres.

Another writer, speaking of exits, remarks that the safety of an audience depends more upon judiciously-arranged means of egress than upon any precautionary system of fire appliances or fire-resisting construction: panic may develop itself at any moment without adequate cause. False alarms and imaginary fears may be productive of a more serious panic than the presence of real danger. "There should be means of escape from the building sufficient to withstand the sudden and extraordinary pressure of a stampede without the exits becoming congested." It has been pointed out that one man alone in topmost gallery would naturally run downstairs to the open air, on the call of alarm, without injury, and that provision should be made for a similar safe exit for a crowd—a difficult problem.

The usages and customs of a London theatre compel the mixing together of certain sections of the audience in one common vestibule, or entrance hall, whether for ingress or egress. For instance, it is customary for the stalls, dress circles, private boxes, and upper circle, to enter by the main entrance, to which is usually attached a spacious and somewhat attractive hall or vestibule, which is used as one of the exits from these parts, each of which, however, should be provided with an additional and separate exit into the street, apart from that passing through the vestibule. The mixing of any two or more sections of the audience within the building is a bad custom, and to avoid any difficulties of egress through a common entrance vestibule, the London County Council's eleventh regulation appears to have been framed.

"Where vestibules are provided not more than three tiers and floors (or where such tiers or floors are divided into two or more parts, such parts of tiers or floors) shall communicate with one vestibule.

"The width of each vestibule shall be at least one-third greater than the united width of all the doorways and passages that lead thereto.

"The united widths of all the doorways or passages that lead from a vestibule towards a thoroughfare or way, shall be at least of the same width as such vestibule."

The necessity of providing exits through a common crush room or vestibule, where the better class of people who frequent the theatre may wait for their carriages, is obvious. The above regulation should secure an uninterrupted exit for each division.

The New York regulations provide a common place of exit and entrance for the main floor of the auditorium and the first gallery, provided the capacity be equal to the aggregate capacity of

the outlets from the main floor and the said gallery.

In St. Petersburg the vestibules must be spacious and surround the *parterre* on three sides, with sufficient number of exits without internal lobbies, the exterior lobbies must be spacious and not less than 7ft. wide. The collective width of the exits on the outside from the vestibule must not be less than 4ft. 8in. for every 150 persons accommodated. In Paris the total width of the openings communicating from the passages to the vestibule must not be less than 19ft. 7in. for theatres containing 1,000 persons, or less. The external doors from the vestibule to the street cannot be less than three in number, with a minimum width of 8ft. 2in. each. Where a theatre contains more than 1,000 persons, 1ft. 11½in. has to be added to this for every additional 100 seats. So far, I have dealt with the question of exits, apart from the consideration of passages, staircases, and corridors—this must follow, as also the special means of arrangement needed in entrances, apart from exits, which will be my next consideration.

"BUILDING NEWS" DESIGNING CLUB.

A SMALL SHOOTING-BOX.

VULCAN is first, "Nil Nisi Bonum" is second, and "Smilash the Goth" comes in third for this subject, which is the last of the 1891-92 series. Now we shall proceed to go over the work of the session, so to speak, and see whose points of merit determine the award of the prizes which we offered.

The following are the conditions printed for the guidance of the competitors:—

A gentleman's small shooting-box, for site on a Scotch Moor, to be built of stone and roofed with slate. The ground line of the land is presumed to fall one in ten from the N.W. to S.E., the latter being the aspect for the front of the house. The accommodation to provide a good porch and entrance hall (12ft. wide), one living-room 24ft. by 18ft., or of that area, and adapted for billiards. A small smoking-room and a gun-room, kitchen and offices, five best bedrooms, and two servants' rooms. No half-timber to be used, and an exposed position is contemplated. Scale, 8ft. to the inch. Two plans, two elevations, section, and view. Plans, if desired, may be 16ft. to the inch. The game larder to be detached from the house.

"Vulcan," in point of style, shows a knowledge of old Scottish work, and the difficulty of obtaining quaint conceits or special detail executed away from everywhere on a Scotch moor has been kept well in mind. The exposed position, too, on such a site necessitates a very simple type of work; while the local mannerism adopted by the author in his composition, if not strikingly original, seems appropriate. The porch screens the hall from the driving rain only moderately well, having openings on its three external sides; and, moreover, as the hall only obtains light from windows opening into the porch, it would not be so light as might be desired. The staircase, too, would gain by having a more decidedly extensive window. In section its size seems ample; but the plan shows a sash similar in width only to those of the living-room. The servery passage also might have had more light with advantage. In a general way we like the plan, and should like it better but for some matters affecting the lighting, as in the points above, or on the bedroom floor, where the lobbies look rather dark. The bedrooms hardly accommodate the beds, as drawn, so well as could be wished, except perhaps in the chamber over the porch. In this room, however, the door opens uncomfortably on to the landing. In the others the bed, considering the area of the apartments under notice, is needlessly close to the doorways. The servants' bedrooms are much better in this respect.

"Nil Nisi Bonum" is decidedly more out of the ordinary in style, and aims, not without a degree of success, at originality. Unfortunately we cannot add that the composition is quite so satisfactory in plan as others which are, perhaps, less original. In a small house, particularly one conceived on a square, long passages are extremely inconvenient. Take the entrance and notice how the servant in admitting visitors must insure all coming into the hall before she can get past, or else the door must be shut in their faces to permit of her going back into the house. Then observe that immediately facing the front door stands a blank wall, a most ugly arrange-

ment, as anyone can see. Again, every time a person calls, those in the house passing from the living room to the first floor have to do so by way of the narrow passage just referred to. Upstairs we reach a long ugly passage leading up to the w.c. door before any of the bedrooms are reached. The rooms are too awkward in shape for sleeping apartments, excepting the one over the living room. The w.c. out of the hall occupies the place which a stranger might mistake for the entrance porch. Externally the elevations are curious, and the little lead flat to the rear of the tower seems but a poor expedient. There is, notwithstanding, a quaintness which at least gives an interest to the composition, and it might, if built, look suitable. We do not say that it is suitable, and, indeed, both designs are rather too ambitious in character. "Smilash the Goth" makes his house too much like a villa intended for the southern parts of England. This is a very common fault with other competitors, few of whom have entered into the spirit of the proposal quite so freely as we could have wished. The wind and sweeping rains on a Scotch moor would soon wreck some of the flimsy and fanciful cottage-orné-like dwellings of which plans have been sent in. What is wanted really are thick walls, and very strong, simple roofs, capable of weathering any storm. "Smilash the Goth" is never, however, careless in important matters, and he has given us in the main a really good house, if only our site had been elsewhere. The w.c. out of the porch is a mistake. The smoking-room in a shooting-box might have led out of the hall, so as not to have rendered it necessary for a smoker on a cold night to come into the open porch before going to bed. True, the verandah connects it with the living-room, but that on a pouring night, would also be a very wet place. There is too much glass in the living-room for such a district, nearly all one side of the apartment being occupied by window. The carvings to the façades are needless. The interior panelling is in good taste and pretty. "Unitate Fortior" sends a capital plan; but it has one serious fault—a dark hall and darker landing upstairs. With a little modification of the gun-room, which is a mere lobby, and the staircase windows both back and front, this objection might have been obviated. The elevations are commonplace, and details of the plan are thoughtlessly contrived. Examples of this are a seat in the vestibule, cutting into the steps up to the hall. Either it must be 2ft. or 2ft. 3in. high, or the top step must be above the seat at the upper end. The chimney corner is in the darkest part of the living-room, and being immediately located between the servery and main doorways, is absolutely without comfort. "Black Prince" has improved. His house would be more at home in Surrey. The gun-room in the centre of the house is not a good position; but for an ordinary residence, the arrangements leave little to complain of, seeing that a drawing-room was not asked for. "Symbol" is neat, and makes a fairly convenient plan, but parapets with narrow gutters are best avoided, and the attics would be very cold. "Sphinx" gives solid walls throughout, but the long passage on the ground-floor is a poor affair. Outside the treatment looks flimsy. "Supervision" is plainer, but ineffective in his design. The kitchen door facing the main entrance is a fault, and the wasteful landing as big as the hall is another. "Clansman" furnishes a dwelling of merit, but it is not a shooting-box adapted for Scotland. The south-east front is pretty with the coupled bays. The flower balcony between is all very well, but destroys the privacy of the two principal bedrooms entirely. "Q. E. F." means to be solid in his work, and with more "go" in his elevations, his design would have taken a better place. We commend him for the simplicity of the entrance-front, which would do well enough, and looks likely to be a success, if executed. "B," in a circle, makes his house look too tall, and it is adapted for a suburban site. The elevations with stepped gables, drawn in brown ink, display taste, but not suitability, for our shooting-box. "Rosenberger" puts himself out of court by ignoring the club rule as to the size of paper to be used. His plan is original and uncommonly quaint, displaying evidence of capability, as do the elevations; but his perspective is quite unworthy of such a designer—indeed, it spoils his work.

We shall hope "Rosenberger" will again contribute, and follow the rules of the club more closely. The other designs come in the following order of merit:—"Ajax," "St. Hughes," "Cottager," "Ivanhoe," "Black and White," "Wyandotte," "Neufardi," "Phoenix," "Yorkshire Tradition," "Box," "Sweet Auburn," "Old Postage Stamp," "Sector," "White Rose," "The Baron's Dwarf," and "Peterborough."

The town council of Weymouth have decided to seek Parliamentary powers to borrow £20,000 for the development of the harbour.

NEW SHOREHAM CHURCH, SUSSEX.*

THIS sketch, taken from the north transept, shows the Norman work of the crossings, and a peep into the elaborate Early English choir. New Shoreham Church was probably erected about 1100, and contains examples of Norman, Transitional, and Early English architecture, besides additions in a later style. When complete it must have been a stately edifice, with a bold cruciform plan. The nave has long been

* We gave a measured drawing of the east end of this church, by Mr. Maurice B. Adams, in the BUILDING NEWS of July 28th, 1871.

destroyed, but substantial evidences of its pre-existence remain. The portions of the church now remaining comprise choir, with side aisles, transepts, and tower. Externally the walls of the choir rise higher than those of the transept, two massive flying buttresses supporting the groined roof.

R. OWEN ALLSOP.

The Chiswick Local Board have applied to the Board of Trade for their sanction to a contract with Messrs. Bourne and Grant for the electric-lighting of the parish, and the contractors are ready to proceed.

PHOTOGRAPHS IN PALL MALL.

THE Photographic Society of Great Britain opened last Monday their annual exhibition of photographs in the galleries of the Old Water-Colour Society, and we may say at once that the collection compares favourably with previous gatherings. The architectural subjects, however, do not strike us as being so important as in previous years either in numbers or in the novelty of interest in the buildings chosen for representation. Mr. J. B. Scott shows an interior of Carlisle Cathedral by a collodion print taken direct from the building. The view represents the vast east window and the choir, but the picture seems wanting in brightness. Mr. Harold Baker is far more happy in his two capital groups entitled "A Few Old Buildings," which include such specimens of historic Domestic architecture as Compton Wynnyates, Warwickshire; Woolas Hall, Worcestershire; and Somershall Herbert, Derbyshire, three charming old dwellings always worth illustrating. He shows a few good interiors, some of which we recognise; but as the subjects have no titles one or two are difficult of identification. Colonel J. Gale obtains a medal, which he richly deserves, for "The Incoming Tide," and sends other admirable studies, such as "A Cottage Doorway" and "Flatford Bridge." Mr. C. Essenhigh Corke, of Sevenoaks, is well represented by some of his beautiful photographs of Knole Park, Kent, some of which we have already illustrated. The whole collection makes a valuable addition to an architect's library. Medals are deservedly awarded to Mr. H. Yeo's subject-picture, "Blowing Bubbles," and Mr. A. R. Dresser takes another for a view of Aylesford. Mr. Harry Tolley exhibits a masterful print of "Limestone Rocks in Derbyshire," and near this another, called "Out of the Marsh a Fir-tree Grew." The grand salon of the Vatican Library is the subject of an unsurpassed bromide enlargement by Mr. Henry Little, showing the arabesques and mural paintings, as well as the splendid exhibits in this national museum, to great advantage and in the fullest detail. The same artist sends a view of St. Peter's, Rome, and a similar, but more specially interesting, study of the south end of the roof of St. Mark's at Venice, giving a bird's-eye group of gables, pinnacles, and skylines. Close by this last frame is a triptych series of smaller photographs, by Mr. Richard Keene in his best manner, of Dunfermline Abbey, showing the north porch, an interior from the N.W., and Major Bruce's tomb by Foley. The first named is exquisite for artistic spirit and treatment of light and shade. Dr. T. H. Morton contributes a set of views from Canterbury Cathedral, including all the familiar points of interest; and Mr. S. Bourne exhibits a big picture of Calder Abbey from the east, illustrating that ruin and the surrounding trees with appreciative skill, making quite a telling picture. "Tired Out," by Mr. H. Stevens, is a character study of a cat and dog fast asleep, which at once appeals to popular fancy, while as a piece of technical photography it deserves special mention. "Worn Out" is a medal picture by Mr. J. E. Austin, taken direct with a spectacle lens. An old man is critically examining an old Dutch clock, and his expression clearly indicates that it is a case of "No go." Mrs. Main secures a medal for six Alpine snow scenes, called "Frost and Sunshine," and no doubt her work is as good as it can be. Mr. A. Kemp obtained a rare specimen of character in the model of "My First Love," an ancient dame of many summers now far advanced in the late autumn of life, and therefore possibly all the fresher in the memories of her distant springtime. Messrs. Elliott and Son show a remarkable green carbon enlargement of a seascape, 7ft. long by 5ft. high, from a whole-plate negative by Birt Acres. It is a study of the waves rolling—

"Break, break, break,
At the foot of thy crags, O sea!"

It is pieced up in three sections, but makes a very remarkable specimen of photographic art, and has easily obtained a medal. The ruins of Netley Abbey furnishes Mr. W. Scorer with a picturesque subject for his fine big view (285), and the same hand sends a large platinum-toned view of Portsmouth New Town Hall, showing that very dignified copy of its prototype at Leeds to great advantage. In reality, the close proximity of the overhead railway almost touching the building seriously mars the Classical repose of the edifice; but this is avoided in the

picture here given. Mr. W. Thomas contributes a lot of small prints which interested us particularly. "An Old-time Garden," with its formality, cut yews, and terraced wall, showing the old manor house hard by. The title is missing, but no doubt remains as to its thoroughly English character and admirable suitability for much that makes the charm of an historic, artistic home. As a striking contrast to this reposeful garden is the landscape gardener's naturalesque showpiece in Mr. Alfred Rothschild's grounds at "Halton," Tring, Herts (286), depicted here so well by Mr. H. Bedford Lemere. The Mansion is an expensive house done in the French chateau style, designed and built by Messrs. Cubitt a few years ago. By way of a formal conceit in the lawn by the side of the park-like approach to the house, we noticed a vast, half-basket-shaped bed some ten feet over, and heaped up to give the rounded form, with a real wicker bottom and handle, the side of the basket form being built up of a series of *Echeveria secunda glauca*, set out to imitate the woven diaper of a basket. In the head of this basket-bed are planted a wealth of all kinds of flowers, growing, of course, at right angles to their supposed container. Handel's Organ in Little Stanmore Church, near Edgware, is represented by Mr. J. H. Gear. This organ was erected by Jordans for the Duke of Chandos, who employed Handel as his Chapel Master, and rebuilt Stanmore (Parva) Church in 1718 in the "stately pompous and uncommon" Classic of the Early 18th century.

"On painted ceilings you devoutly stare,
Where sprawls the saints of Verrio and La-guerre."

Thus wrote Pope in satire, but no doubt La-guerre and Bellucci did decorate the church, though Verrio died ten years too soon. The organ stands in a chamber behind the altar, forming a recess the whole width of the chancel. The opening is, however, only little wider than the altar. The idea for a church is theatrical, but musically the effect is soft and sweet. Handel composed "Esther" here and 20 anthems on this organ. Mr. C. Court Cole, of Oxford, sends a first-rate series illustrating the windows of Christ Church Cathedral, some of which we hope to illustrate shortly. Herr J. B. Obernetter, of Munich, sends some photographs from Albert Durer and Rembrandt's drawings and etchings, which are highly interesting, and the Autotype Company show another of "Christ in the Carpenter's Shop," from the mural painting by Mr. W. B. Lance, which we illustrated on Feb. 5th last from St. Mary's School, Wantage.

A NEGLECTED CHAPTER OF ARCHITECTURAL HISTORY.

THE names of Alan of Walsingham and William of Wykeham are familiar to every student of English architecture. Each was an ecclesiastic of high rank—Walsingham was Prior of the great convent at Ely, and Wykeham was Bishop of Winchester. And each was an architect who really designed and executed the works which bear his name, and did not, like so many other Mediæval ecclesiastics, simply get the credit due to nameless artists who worked under his nominal control, or worked with money which he had given or bequeathed. Alan of Walsingham actually designed and constructed the famous lantern over the crossing of Ely Cathedral, and the beautiful Lady Chapel which adjoins the church, while the architectural record of Wykeham is as well attested and covers a much wider field. When, at the age of twenty-three, he was first presented to King Edward III., this priest already had a tested skill in architecture; at the age of thirty-four he was given charge of all the royal works at Windsor, where he built the new ward of the castle and the chapel for the Order of the Garter; he renovated many other fortresses and constructed a new one at Queenborough at the mouth of the Medway; while Dean of Saint-Martin's-in-the-Fields in London he rebuilt his church (where the Post Office now stands); and while Bishop of Winchester he reconstructed the nave of his cathedral, and built, as well as paid for, Winchester School and New College in Oxford.

Walsingham's work was done in the second quarter of the 14th century, when the Decorated style had passed into its second or "flowing" stage. Wykeham, who was born in 1324 and died in 1404, was the most active agent in the

establishment and early development of the Perpendicular style. Both, therefore, belong to the later period of Gothic art, and when this fact is remembered, the figures assume a typical significance. In addition to their personal interest, as the figures of great architects, they have a representative interest as illustrating the English architectural profession in their time, and as enabling us to compare it with the French architectural profession of the same time. And such a comparison broadens and deepens in significance as we grow to understand that it illustrates the whole course of Mediæval architectural development in the two countries, and that this, in its turn, illustrates broad national developments in the most striking way.

The names of Walsingham and Wykeham show that, down to the very last days of Gothic art, a state of things existed in England as regards the erection of great buildings which had ceased to exist in France centuries before; and when we ask the reason, we find it in the different political and social conditions of the two countries.

Look into every French history of Mediæval architecture and you will find it arranged under two general heads: *L'architecture romane* and *L'architecture gothique*, or *ogivale*; and in English books you find these same headings: Romanesque Architecture and Gothic, or Pointed Architecture. But certain other corresponding terms are used in French which are never used in English. In French we constantly find *l'architecture monacale* used as a synonym for *l'architecture romane*, and contrasted with *l'architecture nationale*, which is a synonym for *l'architecture gothique*; and the latter is always referred to as the work of *architectes laïques* (lay architects). But in English the terms "monkish architecture" and "national architecture" have no such accepted significance, and I do not remember ever to have met with the term "lay architect."

We cannot be surprised to find that the main points of unlikeness in the Mediæval stories of France and England lie embalmed in this dissimilar architectural terminology; for architectural history, all commentators are ready to tell us, is the plain record in stone of those same facts of inheritance, influence, desire, and aptitude which stand out prominently upon written records. Nevertheless, while French general historians rarely neglect to illustrate their chapters by references to artistic developments, and while French historians of architecture carefully and fully explain its dependence upon political and social conditions, English authors have by no means done the same. Among writers of English, few general historians, except Prof. Freeman, have laid stress upon architectural facts; and, so far as my reading extends, no historian of architecture has traced the relationship between English national life and its artistic developments, or has attempted to contrast the different social influences which worked upon architecture in France and in England. This is my excuse for offering the following very brief and fragmentary sketch, which, I trust, another hand may elaborate, as I am sure it deserves to be elaborated.

When the Frankish hordes swept over Gaul, Roman civilisation was not wiped out. The old Roman centres of population survived; the old cities lived through the tempest, although, of course, physically and intellectually, in a shattered condition. They naturally remained what they had naturally become—the centres of the Christian faith; and there was never such a break in the life of the French Church as there was in the life of the British Church. In Britain, all memories of Roman rule, and all relics of British-Roman civilisation, were swept away in the deluge of heathen Englishmen (Anglo-Saxons, we often call them), who remained heathen until—a century and a half after their first landing—St. Augustine and his monkish missionaries came from Rome to preach Christianity afresh. Only a very few of the greatest towns, like Lincoln and York, still continued to exist. The new rulers often had not even a nominal capital. They were rulers of tribes, not of districts; and while the early Christian bishops of Gaul had naturally seated themselves in the old municipal centres of temporal power, the early English bishops seated themselves as nearly as possible in the geographical centres of the tribal settlements they were to evangelise—occasionally in the wreck of a town, more often near some isolated missionary monastery, and sometimes in a savage spot where a monastery or a great

collegiate house grew up around them. Thus, while we always find a French cathedral standing in a city which has some importance now and once was very important, we often find an English one encircled by a town to which it first gave birth, and which may or may not since have grown into greatness. Little Wells and Ely, considerable Lichfield and Salisbury, and big and busy Durham—all alike are the direct creations of cathedrals which were founded amid wild and desolate surroundings.

The municipal organisations which thus played a so much greater rôle in early France than in England, continued to play a similarly important rôle all through Mediaeval times. For a long period the history of what we now call France is a history of rival, warring towns and dependent districts; while the contemporaneous history of England is a history of rival, warring parties, without definite local affinities.

But in the general riot and darkness which marked the ruin of Charlemagne's empire and threatened once more to extinguish civilisation, the cities of France were eclipsed for a time, while the schools which Charlemagne had founded in connection with ecclesiastical establishments survived where these establishments lay a little aside from the great currents of internecine strife, and became the only nurseries of religious and secular knowledge. Then, in the very darkest moment of all, toward the end of the 10th century, when the world was waiting, affrighted, for its predicted end in the fatal year of 1000, the new monastery of Cluny was founded; and all through the 11th century its great hearthstone of intellectual life glowed more brightly than any in Western Europe. In the monasteries, and nowhere else, were libraries and schools, workshops of art, and laboratories of science; and from them, and especially from Cluny, went forth the men who, as the land began to calm itself a little, taught the burghers of the towns and built their churches for them. So the architecture of this period, the Romanesque period, is rightly called *l'architecture monacale*, as developed and exclusively practised by monks.

But gradually, thanks to the efforts of these monks, intellectual life began to awaken in the towns. It quickly meant a passionate protest against the iron hand of feudalism, a passionate desire for liberty; and in men of semi-Gallic blood, strongly tinged by Roman influences, this desire naturally expressed itself in struggles to secure a measure of civic autonomy.

Feudalism never pressed so heavily upon England as upon France. There the great nobles never became so powerful that the king was simply the greatest among many who openly defied his authority; there they never stood so thickly between the people and the king that local matters seemed all in all, and national consciousness scarcely existed; and there no old traditions of civic importance and independence persisted. The men who faced King John wanted, not to be free burghers, but to be free Englishmen; local interests were not made prominent; what they accomplished was done for the realm at large; and barons as well as bishops were their natural leaders. But the burghers of France faced, not the king, but their local *seigneurs*; and what they wanted was to be citizens of self-regulating *communes*. There was a great barrier to be broken down in France before king and people could help each other, or even oppose each other; and this barrier was formed of the nobles, who opposed the people on the one hand, and defied the king on the other. The story of this period in the land we now call France is extremely interesting but extremely complicated. Four contestants are in the field; the burgher, the noble, the churchman, and the king; and they perpetually appear in new combinations, in a veritable kaleidoscope of changing alliances and resistances. But, in general, the burgher, the churchman, and the king each felt that the noble was his most dangerous foe; as a rule the king favoured, or professed to favour, the *commune*, at least until he thought it was getting too powerful in its turn and, unless the bishop was himself the temporary *seigneur*, he was the friend of his flock. We can see to-day that king, churchman, and burgher were all fighting together for the great result which St. Louis saw in the 13th century—a united nation whose *communes* should possess a fair measure of local freedom. But at the time it must have seemed indeed a welter of conflicting interests; and, of course, it was interests, not true sympathies, that brought

about temporary alliances, now of one sort, now of another. For example, as the monasteries were locally dissevered from the seats of Episcopal authority, so they sought to free themselves from Episcopal rule; increasing in power and wealth, worldliness and ambition, they tried more and more for an independence which would mean no over-lord but the Pope himself; and thus, to strengthen his arm against this enemy within the church, the bishop was again forced to labour for the burghers' advantage.

Meanwhile there were towns, of course, in England, and growing local interests and local oppressions and resistances; and gradually the townsmen claimed and won many new rights and privileges. But these were not usually political privileges; municipal matters were not bound up with broad national concerns as they were in France; and so, while the French burgher in his greater need used ducats and arms together, the Englishman could conquer with peaceful ducats alone.

Now let us see how these social facts expressed themselves in art.

In England the cathedral chapter was often monastic, and even when it was not it had an almost monastic size, dignity, and individuality. But in France, although a monastery might lie close to a cathedral town, it had no concern with the cathedral which stood in the heart of the town and was the core of its life, the focus of its interests, the property of its citizens, and, as the new order of things advanced, the work of their hands and the shrine of their liberties.

No great municipal halls existed in those days, and Frenchmen could not remember them, so wholly had the tradition of the basilica become the history of the place of worship, so entirely had architecture become the handmaid of the Church. On the other hand, great popular assemblages, held in-doors or out-of-doors, wherever the people might think best, were unknown even to farthest tradition in France; the noble institution of the folk-mote was an inheritance of purely Germanic peoples only. So when the need for large meeting-places arose in a French town, it wedded itself to the idea of the old architectural centre of the town, and the cathedral became not only the symbol but the actual fosterer of civic as well as of religious life.

Meanwhile, with the general development of wealth and intelligence, architecture began to stir itself for a new departure. The old Romanesque scheme, developed and practised by monks, was putting forth new buds, and laymen's hands were to unfold them. The earliest buildings which show the pointed arch used in what may be called a Gothic way were built by ecclesiastics, like the famous church at St. Denis, whose architect was the Abbé Suger. But the people soon learned all that the Church knew of science and art; their minds were more alert and plastic than the clerical mind; their hands were not cramped by semi-artistic, semi-ecclesiastical traditions; their spirit was fresh and vigorous; the new and larger churches which they wanted appealed to all that was strongest and best in their natures, and not to religious zeal alone; and so, with a mighty impulse, they took control of art, and an architecture which may truly be called an *architecture nationale* passed, in the brief space of fifty years, from its embryonic to its perfect state. Of course the bishop and the church at large were not ignored; but, while the bishop permitted and, perhaps, directed the building of the cathedral, a layman was its actual architect, guilds of lay carpenters and masons raised its walls, guilds of lay sculptors and painters and glass-makers adorned them, and the people chiefly paid the cost, and often men, women, and children together worked with passionate enthusiasm upon the structure which was at once the temple of their faith, the sign of their city's greatness, and the hearthstone of their liberties. Romanesque art—monkish art—was dead. Gothic art—national art, the art of laymen—had taken its place.

Thus local liberty and architectural art drew a fresh breath of life together, and developed hand in hand. And when feudalism had followed monastic architecture to the grave—when national unity and local freedom were finally achieved—art had its splendid share in the triumph. Gradually, as the kingly power extended over the provinces once ruled by rebellious vassals or rival princes, and as the *communes*, measurably content, ceased from local strife, cathedrals were built by the king's command,

and provincial manners of design, so strongly marked in the Romanesque period, gave way to the Gothic style, which had been born and developed in the old *domaine royal*. Cathedrals which are French structures in that strict architectural sense which gives to "France" its early and limited significance as denoting the *domaine royal* arose in all parts of what is the wide land of France to-day, planted, as a Frenchman had said, like royal standards of victory in every great annexed town. But, as this form of art had been developed by the *communes*, so it was the help of the *communes* which had enabled the king to triumph over the great provincial nobles, and thus the Gothic cathedrals which we see in places as far apart as Coutances, Bordeaux, Limoges, Clermont-Ferrand, and Narbonne were standards of the people as well as of the king, trophies of the popular struggle for freedom no less than of the royal struggle for power, proofs of national unity, but at the same time of the achievement of local liberties. Truly, he who reads this chapter of architectural history with care reads the life history of the people who wrote it.

As the corresponding English chapter is equally interpretative, it naturally has a very different accent. Where cities were of much less importance, where local matters had small political significance, and where episcopal chairs were set in the midst of great cloistered houses, the burgher had neither the need nor the chance to make cathedral-building his concern. Whatever part bishop or burgher might take in the great national struggle, he played that part on a national battle-field; the cathedral stood aside, built by its clerical owners, and serving these owners first, and the people only in a secondary fashion. Cathedral priests might quarrel and fight with the townfolk, but the townfolk did not question ecclesiastical supremacy within the cathedral itself, as did the burghers of Laon, of Rheims, and of many another French *commune*. The clergy of England owned its cathedrals as truly as those great abbeys which contained no episcopal seats. Naturally the people must have taken a pride in them, and may have helped a little in their construction. But their interest must have been of a simply religious sort, and we are not told that it ever approached that frenzy of enthusiasm which is shown by the oft-told story of the building of the Cathedral of Chartres. The fact seems to be that, down to the very latest days, the bishop, the abbot or prior, and the "house," practically bore all the cost of their church; the enterprise was theirs, and the glory was theirs; and from their own ranks they drew the executives whom they required. Of course, there were secular guilds in England too, and there may well have been some lay architects. But English historians of art take no notice of these guilds, so prominently described by French historians, and never attempt to draw a line between the work of churchmen and the work of laymen; and the guild of masons makes a very small showing even in general account of English trade corporations, while we know what we term "freemasons" meant upon the Continent. And, again, we have a long-extending if scanty list of English Gothic architects, not ending even with Walsingham and Wykeham, who were certainly ecclesiastics, and no list of identified lay architects to set against it, while in France clerical names cease entirely to appear after the dawning of the 13th century. The builders of Amiens in the early 13th century are well known by name, and they were laymen; and even William of Sens, who, at a much earlier day, brought the infant Gothic style across the Channel, came without frock or tonsure from the building of the cathedral in his native town to the building of the choir of Canterbury.

It is thus that such names as those of Walsingham and Wykeham assume a typical significance. They are the names of those who were the greatest architects of their land and day, generations after the arts of France had passed out of clerical control. And when we do not know the actual name of an English architect—when we simply know that some unspecified artist did the things which careless mouths attributed to some prior or bishop—still we must imagine him a local ecclesiastic of lower rank, not a layman like his contemporaneous brother across the Straits. There were probably, I say, exceptions in both countries; probably certain laymen worked upon the cathedrals of England and certain clerics upon the cathedrals of France. But we cannot perceive their figures

or trace their influence at this distant day. The great picture which history reconstructs for us in France is a lay profession assuming control at the very birth-hour of Gothic art, and in England a clerical profession keeping control until the very death-hour of Gothic art. So far as I have been able to discover, the first English cathedral which can be called a "national" work in the symbolic sense, which was the creation of laymen and not of the church, was Sir Christopher Wren's St. Paul's.

I think no impartial student of Mediæval architecture questions the immense superiority of French over English Gothic. It is a superiority which shows in every form and phase of the art, from the conception of the structural body to the last minutiae of carved or painted decoration. It speaks alike in a much loftier degree of constructional ambition, a much more logical grasp of constructional expedients, a richer desire for ornamental finish, a deeper imaginativeness in design, and a completer skill in technical execution. Not from one single point of view or from another, but when studied in any of its details French Gothic is at once a nobler and a more perfectly developed art than English Gothic.

Is the explanation to be found entirely in a difference between innate artistic endowments? Or may we read it partly in the differing developments of the artistic professions? Were English Gothic artists inferior to French Gothic artists simply because they were Englishmen, or partly because they were ecclesiastics? The relatively slow development of the English form of Gothic; its lingering attachments for Romanesque precedents, its inability wholly to throw off the traditions established by early clerical builders, to grasp the new structural idea conceived by the laymen of France, and to carry it boldly to its utmost limit; its timidity and lack of logic in constructional design; its deficiency in imaginative power and in technical skill as regarded decoration—may not these characteristics be plausibly traced, in part, to the fact that the Church was always the artist?

Church establishments were the only possible nurses of science and art in the early Mediæval years. But as the world outgrew the swaddling-bands of the Church in other directions they may well have pressed with hurtful force upon art. The ecclesiastic who was an architect could not, like his lay rival, be that and nothing more; nor could he so readily travel about, see what was being done elsewhere, and develop his artistic gift; nor could he train up his own children to follow in his path, as we know that certain great French architects did. He could not be a member of a well-trained, well-regulated profession in which each artist was bound by what others had taught him, what others were doing, what others were trying to do in novel directions. In later Mediæval days the secular guild must have been a much better nurse of art than the clerical house, because it bestowed more freedom on the one hand, and, on the other, better training, wider experience, stricter artistic ideals. When we know that even the Late Gothic architects of England were still ecclesiastics, we can better understand both the general conservativeness of English art and its occasional breaks into lawless individuality. We can better understand why the Gothic constructional scheme never fully developed, but a lingering Romanesque element always remained embedded in Gothic walls, and why no great school of sculptors, comparable to those which dowered so lavishly almost every province of France, grew up on English soil. And, on the other hand, we can better understand how, while a general, logical development, unmarked by strong individual eccentricities, went on in France, we find here and there in England such bold pieces of personal experimenting as the portico at Peterborough, the Galilee chapel at Durham, and the ornamental casing of the choir at Gloucester. There was a school of architecture in France, in the widest yet the strictest meaning of the term, and it was possible, because art was in the hands of lay corporations. There was no such school in England—may we not think, partly because art was in the hands of the clergy?

The absence of the broad and plastic, yet very logical, exact, and universally respected, incitements and restraints of a true school shows, I repeat, alike in the general conservatism of English Gothic and in its occasional lapses into bold, individual experiments. No church even approaching Amiens as a perfect, logical illustra-

tion of the Gothic ideal ever arose in England; but there is nothing in France which, for striking individuality, daring personality, approaches the portico of Peterborough. When we examine Amiens, we feel that a whole race of men of genius, carefully trained to work together without undue self-assertion, is revealed by its existence. When we examine the portico of Peterborough, we feel the presence of a single man of genius, who was not logically-minded, and, therefore, was not a very well-trained architect, and who worked without a thought of what anyone else was doing. The same impression is given by many other parts of English churches, except that we do not always feel that genius had a hand in them. And a similar impression is given even by the famous lantern of Ely Cathedral. Its idea was Walsingham's own—this idea of widening out the square crossing into an octagon, and crowning it with a domical roof. It was his own, and it was a truly logical, truly Gothic, and admirable idea, very different from the semi-pictorial, wholly illogical idea of the unnamed creator of the Peterborough porch. But its execution betrays a lack of logic in minor matters, and of perfect skill in execution, which we should not find had a similar idea been expressed by a French architect of the time. No French architect of the 14th century would thus have simulated a stone vault with wood, and none would have designed the narrower diagonal walls of the octagon in so weak and inorganic a way. The idea is very fine; the execution, I venture to say, is in some points amateurish. At Peterborough the idea itself, despite its imposing grandeur, is amateurish from the architectural point of view. And the same term often comes to mind when we study the great churches of England one by one, or contrast them all together with the great churches of France. Is it fanciful to think that this may be partly because, while French Gothic developed under the hands of laymen, and so became a truly national art, English Gothic developed under the hands of churchmen, and so never became in the same sense a national art?

Of course, there is another way of looking at the question involved. We may ask, not whether national aptitude was partially stunted in England by clerical control of the arts, but whether national inaptitude was proved by the persistence of this control? We may ask whether, had the English been a truly artistic people, they would have suffered their arts to remain in the hands of the clergy? If the 12th-century Englishman had been as artistic as the 12th-century Frenchman, would he not have felt an irresistible impulse to seize the helm of artistic progress himself, even though he was not prompted by that strong civic feeling which ruled in France—was not bound into ambitious, powerful communities by the local power of the nobles on the one hand, and, on the other, by the persistence of the old Roman municipal idea?

But, after all, it is not profitable to speculate upon possible aptitudes which never reveal themselves. The truest significance of the story of the development of Gothic art in France and in England is its proof of how vitally outside influences affect architectural development, how much more dependent it is upon what we may call sociological and what we are pleased to call purely æsthetic influences. Some may fancy that Gothic art developed as it did in France simply because the Mediæval French were a nation of great artists who cast about in their minds for an ecclesiastical ideal and then proceeded to realise it. But the careful student knows better than this. He finds that the first tentative steps to progress from a perfected Romanesque towards the perfected Gothic style were taken by clerical builders who were trying to discover more manageable ways of roofing their churches than by the use of the barrel-vault. Then he finds that, prompted by a newly acquired intelligence, a newly developed love of freedom, and a newly enlarged pride in their native towns, the burghers of France took art out of the hands of the ecclesiastics, just as they took the control of their private affairs out of the hands of their feudal *seigneurs*. Then he finds that, as space was needed in the cathedral nave for secular assemblages, the cathedrals were built much larger than before; and then, that, as each commune succeeded more or less well in its political ambitions, it grew ambitious in other ways, and, desiring to assert itself as the equal of any neighbour, clamoured for a cathedral which should surpass its neighbours' cathedral, and then he

divines that, as the burghers paid for their churches themselves, they naturally wanted to get as much display for as little money as possible. Finally he sees that when artists became laymen they could organise into lasting associations and yet travel about, learn what their fellows were doing, and work first for one commune and then for another, thus assuring the best chance of a rapid yet logical, homogeneous and uncentric development of art. The Gothic cathedral in its perfected form is a triumph of science and a triumph of economy as well as a triumph of beauty. And it became so because of the favouring pressure of political and social conditions. Similar conditions did not exist in England, and a similar result was not attained there. We may grant all the influence we choose to innate artistic aptitudes, and may as readily grant that, in all kinds of work in every age, Frenchmen have proved their possession of nobler artistic aptitudes than Englishmen.—M. G. VAN RENSSALAER (in the *American Architect and Building News*).

A NEW BRIDGE AT VAUXHALL.

AT Tuesday's meeting of the London County Council, a report was presented by the Bridges Committee, recommending the construction of Vauxhall Bridge and the erection of a temporary bridge. The report stated that Vauxhall Bridge was opened in 1816, built at a cost of £259,681, and purchased by the Metropolitan Board of Works for £75,000. The bridge was of stone and cast iron, and crossed the river by nine arches, each of 78ft. span, supported by eight piers, each 13ft. wide, above low-water level. The piers thus occupied about 104ft. of the waterway, or about one-eighth of the total width of the river between the abutments. The length of the bridge was 809ft., and its width between the parapets 36ft. 6in., having a carriage-way of 24ft., and two footways each 6ft. 1½in. wide. The gradient over the bridge was 1 in 35. The gradient on the Middlesex approach was 1 in 29, and that on the Surrey approach 1 in 30. A considerable improvement might be effected in facilitating the passage of heavy traffic over the new bridge by the reduction of the surface gradients to about 1 in 62, and by the adoption of wood pavement. The bed of the river in this locality was gradually deepening, and the ebb tide was dangerous to navigation. The traffic over the bridge had greatly increased. The bridge that the committee suggested should take the place of the existing structure was a five-arch steel bridge with granite-faced piers and abutments, the width between the parapets being 80ft. The cost would be about £380,000. To accommodate the traffic during the rebuilding of Vauxhall Bridge, the committee proposed that a wooden bridge, not less than 50ft. wide, should be erected, to cross from the extreme western end of the Albert Embankment to Millbank. The cost of the temporary bridge was estimated at £30,000. The report was adopted, with the addition that steps be taken to obtain from Parliament authority to raise an equitable proportion of such cost by an improvement rate on the owners of ground values in the county of London.

CHIPS.

Sir J. B. Maple has offered to present twenty-four acres of land to the city of St. Alban's, to be used as a recreation and cricket ground. The site is a field in Hatfield-road, now used for the holding of fêtes.

An exhibition of drainage and sanitary appliances is on view at Hornsey, having been arranged and brought together by the surveyor to the local board, Mr. T. de Courcy Meade, past-president of the Municipal Surveyors, &c., Association.

The council of the corporation of the Church House have been enabled to resume the building of the great hall, which was begun in June of last year, when the foundation stone was laid by the Duke of Connaught. The impossibility of obtaining possession of some houses remaining on the site caused an interruption in the work, but this difficulty has been overcome, and considerable progress has been made during the past month in excavating and preparing the ground for the foundations. The cost of the great hall, with the adjacent rooms and offices, is estimated at £40,000, towards which nearly £30,000 has been subscribed or promised. We illustrated the building from Sir Arthur W. Blomfield's designs in our issue of May 2, 1890.

MANCHESTER TECHNICAL SCHOOL COMPETITION.

THE selected design for these new buildings was illustrated last week in our pages by a view and plans. Herewith we publish drawings of the second and third premiated designs. By these means the relative merits of the compositions chosen by the professional referee, Mr. Alfred Waterhouse, R.A., for prizes can be readily compared by our readers, and no doubt the details of these plans will be useful to many who are interested in Polytechnic building. Having already given a review of the competitive designs, little remains to be said here, particularly now that the drawings which we reproduce to-day readily explain the main intentions of their authors. Messrs. Gibson and Russell won the second premium, and Messrs. Runtz and Farrow the third. Next week we shall give illustrations of the fourth premiated design, with further illustrations of the chosen design.

"BUILDING NEWS" CLUB DESIGN FOR A SMALL SHOOTING-BOX.

(SEE description on page 450.)

NEW CLUB UNION PREMISES, HOLBORN, W.C.

THE position for this central club-house adjoins, we believe, Holborn Town Hall, and the cost of the work, including the site, is officially stated at £16,000. A more convenient spot could not have been chosen. Outside the door run trams and 'buses to a late hour of the night, and a short walk takes the club member to Farringdon-street Station. Four floors and a basement comprise the front building, which is about 40ft. square, and above the caretaker's rooms are arranged. The ground floor will be occupied by shops and an office for the use of the union. The first floor will be devoted jointly for the committee of the union and the "Women's League," the upper floors being available for letting as private offices, and should readily be occupied in such a position of London. To the rear of the building shown by the architect's drawing, herewith reproduced, will be located the affiliated clubs' comfortable club-rooms, solely for the use of persons holding union pass cards. This is a new idea with many club-men, and is one that will commend itself to all progressive men. The liberal catering found in music-halls, theatres, and other places of amusement, has always met, we are told, with beneficial results, and the official report adds, "Give the club-men of London a central meeting-place, with everything

round them to make them feel comfortable, and there will be no lack of visitors. Now to clear up some misapprehension. It has come to our ears that some clubs in the centre of London are looking askance at the scheme, under the impression that their members will leave them to join the Union Central Club. Instead of drawing members away from the neighbouring clubs, there is much more likely to be an increase in their membership, as persons not belonging to a club, and wishing to join this, will be instructed that they must go and become members of an affiliated club." Mr. W. D. Caroe is the architect of the building.

THE NEWCASTLE-UPON-TYNE CITY LUNATIC ASYLUM—PROPOSED EXTENSION.

THE accompanying design was placed second by Mr. George T. Hine in the recent competition for the extension of the present asylum, and is arranged to accommodate 350 male patients, the female patients being provided for in the existing building. The wards are in four blocks on the S. side of the main corridor, and have throughout a southern aspect, every day-room and dormitory being cross-ventilated, the sick and infirm, recent acute, turbulent, and epileptic cases respectively occupying the ground floors, whilst the chronic, mild, and working cases are placed on the first floors. The administrative department is placed centrally between the old and new buildings for use in connection with both, and the general store and kitchen departments near the dining-hall. Suitable accommodation is provided for the assistant medical officer, steward, storekeeper, attendants, domestic servants, &c. The recreation-hall and chapel are separate buildings, placed between the male and female departments of the asylum. The medical superintendent's house is on the south side of the main corridor, and cottages for ten married attendants near the entrance. Suitable workshops and general delivery yard are provided, and an isolation hospital and mortuary are shown to the north. For the warming and ventilation, a system of propelling warmed fresh air, drawn from a height, into the various wards, corridors, &c., the vitiated air being extracted at about floor levels, and carried by shafts into the ventilating towers, is adopted. The estimated cost is £64,636. The authors of this design are Messrs. Montgomery and Carr, 42, Grainger-street, Newcastle-on-Tyne. We illustrated the chosen plan for this work in the BUILDING NEWS for Aug. 5th last.

SCULPTURE FROM THE ROYAL ACADEMY AND THE PARIS SALON.—"THE CHILDREN OF THE WOLF."

MR. GEORGE FRAMPTON'S striking group formed one of the most conspicuous features in the Lecture Theatre at Burlington House during this year's Academy Exhibition. The subject shows the twin sons of Sylvia, a vestal virgin, and the god Mars, Romulus and Remus, borne by the king's shepherd, Faustulus, who found them exposed in a boat on the river Enipeus. The herdsman took them to his wife, who brought them up, and it is said they slew Amulius, their great uncle, who had caused them to be exposed. The Greek legend of Tyro relates that she also had an amour with Poseidon, and that, as in the intrigue between Mars and Sylvia, two sons were born in consequence. The fable of the wolf suckling the outcast infants is wholly worthless, and as for the etymology of the word Rome, "we need no Romulus to account for Rome."—From the Salon we give the fine portrait statue of the late Cardinal Manning, by M. G. de Bengy-Puyvallée, of Paris. The archbishop, in the ample robes of his Episcopal office, holds the pastoral staff, the ensign of his jurisdiction, and is shown in the act of benediction.

TWO VILLAS, SUREITON.

THESE villas, which are well and substantially built, and are now close upon completion, have the fronts of red brick and natural colour cement, rough cast. Clear leaded pattern glazing has been used in the lights above transoms, &c., and the front door, which has been set back to form a porch, is glazed with plain stained obscure leaded pattern glazing. Each villa contains two reception-rooms, kitchen, and good offices on the ground floor; four bedrooms, bath-room (hot and cold), w.c., and cupboards upstairs. The decorations for the interior, though simple, have all been selected with a view to an artistic harmony. The rent has been fixed at £34 per annum each. A very slight modifica-

tion of the front has been made. The contract price was £776 for the pair; Messrs. Adkins Bros., of Surbiton, being the builders. The architect is Mr. R. Lano Pearce, M.S.A., of 100c, Queen Victoria-street, E.C., and Surbiton Hill.

FITTINGS IN MR. E. DOUGHTY'S HOUSE, NOTTINGHAM.

THE chimneypiece and dressing chest shown on this page have been recently executed by Messrs. Oldham and Knight, from the designs of Mr. Gilbert E. Doughty, architect, for "The Forest," Nottingham, the residence of Mr. Edwin Doughty. Little need be said, as both sketches explain themselves. The bath-room chimney-piece is simple and appropriate; and there is a pleasing and successful attempt, in the case of the dressing chest for bedrooms, to break away from the commonplace article of furniture that usually does duty in this respect. The arrangement of small drawers between the two cupboards is, we think, a good idea; and so also is the working-in of a space for a few select books in the upper portion, and the shelving for ornaments.

THE SKETCH CLUB OF NEW YORK.

THE chamber interior given herewith is a design by Mr. Frederick R. Hirsch, for which he was awarded the first place in the above competition. Whatever may be said against the old-fashioned four-post bedsteads closely curtained, on sanitary grounds, it is certain that for large apartments they bear a far better relative scale, and add a greater dignity to them. The great bed in this sketch is quaintly designed, and one can best appreciate its value by conceiving its place occupied by the more cleanly, but generally hideously ugly, heavy brass bedsteads of modern usage. Differences of opinion may exist on this point, but few will question the merits of the charming chest of drawers, divided in a novel manner into two parts, a handy cupboard taking the place of the usual small drawers. The high-back chair of Jacobean character is also appropriate, though, perhaps, less original than the other furniture. Our illustration is taken from an *American Architect* sketch.

CHIPS.

Alterations have been made to the council-chamber, Walsall, embracing the ventilation, which is now carried out on the Boyle system, the latest improved form of the self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

Messrs. Prescott's bank, London, is being warmed and ventilated by means of Shorland's patent Manchester tiled stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

The foundation-stone of new national schools, Langley, Worcestershire, was laid on Monday last. When completed, they will accommodate 400 children. The architect is Mr. F. Boston, of Birmingham, and Mr. J. Light, of Langley, is the builder.

A meeting of the committee of the Archbishop Thomson Memorial Fund was held in Archbishop de la Zouche's Chapel, York Minster, on Friday, the Bishop Suffragan of Beverley (Archdeacon Crosthwaite) presiding. The meeting was called for the purpose of consulting Mr. G. F. Bodley, A.R.A., the architect, and of considering a new design submitted by him for a recessed altar tomb. This was ultimately accepted, subject to certain modifications, and the selection of a sculptor to execute the effigy.

At the last meeting of the Bermondsey Vestry it was resolved that an engrossed vote of thanks be given to Mr. George Elkington, F.R.I.B.A., in recognition of the courtesy, fidelity, and gentlemanly conduct exhibited by him during the 38 years he had held the office of surveyor. Mr. Elkington, in reply, expressed his thanks, and remarked that no member of the board was now living who was a member when he took office. He had always been proud to be associated with the vestry in doing what he could for his native parish of Bermondsey.

St. John's Brine Baths, Droitwich, the gift of Mrs. J. Dyson Perrins, were opened on Tuesday. The building is Gothic in style, and is situated in St. Peter's Walk. It comprises dining and sitting-room for men and women, kitchens and offices, matron's rooms, and bedroom accommodation for thirty-two patients. The architect was Mr. John Douglas, of Chester, and the builders were Messrs. J. Wood and Sons, of Worcester.

In the case of Charles Dart, of Saltash, Cornwall, builder, the discharge from bankruptcy has been suspended for four months ending Nov. 13, 1892.

WAYSIDE NOTES.

SOMETHING has happened at the Tower Bridge. On Wednesday morning I noticed flags gaily flying, and other evidences of a red-letter day. Being by the appearance of the bridge, the smiths and engineers have completed their share of the work. Possibly the last rivet has been clinched, or the final bolt screwed home, and the artificers on the job have emulated the country bricklayer, who displays his red handkerchief when he has laid the last brick. From a distance the ironwork of the bridge certainly looks complete, and as at present existing, exhibits a natural engineering design. I find that even the public can appreciate the folly of the sham Mediæval towers, and understand that with a little modification the natural iron skeleton could have been made sufficiently architectural *per se*. However, the masons progress with the towers, and soon one of the most notable examples of lack of principle in 19th-century design will be complete. It will surely be the climax.

I see that Chertsey Bridge is now considered to be in such an unsafe condition that it has been closed against all vehicular traffic, arrangements being made for improvising a ferry for foot passengers in case the bridge should be wholly closed. The inhabitants of the district are agitating for an iron bridge to supersede the present one, which is of stone.

The subject of bridge-building occupied the major part of the attention of the London County Council at their first meeting after the recess. Vauxhall Bridge has long been insufficient for the demands it has to meet, and the Bridges Committee of the Council recommend its reconstruction. In place of the nine arches of cast iron now existing, and the great waste of water area by the numerous stone piers, the plan of reconstruction embraces a five-span bridge of steel, with granite-faced piers and abutments. The present bridge is only 36ft. 6in. between the parapets, while that proposed will be 80ft. The traffic over Vauxhall Bridge has greatly increased during the past year or two, and the widening should benefit those who habitually use the bridge. Of course, the Council cannot pretend to make any sort of Metropolitan improvement without endeavouring to institute some method of paying for the works not in accordance with the views of fairness of ordinary persons. "Betterment," indeed, seems to be to the London County Council what King Charles's head was to Mr. Dick's Memorial. It will crop up sooner or later. In the present instance, it is true, the betterment is of a peculiar kind, and partakes rather of the nature of an attempted imposition on the ground landlords of London. Some day, I suppose, we may get a County Council that will confine itself to municipal works, and leave political questions to Parliament.

I trust that we are not going to have further strikes in the building trade this winter. The manifesto of the Navvies, Bricklayers, and General Labourers' Union points towards a repetition of the difficulties of last winter. It has been pointed out as within the bounds of probability that we may have a winter which will go hard with those out of employment. Trade generally is bad, and may be worse, and the occasion does not seem fit for working men to hazard losing employment. If differences can be amicably settled between employers and men, it will be exceptionally a matter for congratulation. An extended strike in the near future must be disastrous to all concerned, contractors and their employes alike.

Aroused, doubtless, by the proposed removal of the Inman Line to Southampton, and the efforts of the seaport towns to establish a Transatlantic service, the Mersey Docks Board contemplate building a new landing stage at the extreme north of the River Mersey, which will be available at all states of the tide for the debarkation of American passengers. The proposed landing-stage will do away with the trouble of transferring passengers and their luggage across the town to the North-Western line, as the railway company, by constructing a small line, may connect the stage with the whole of their system. The matter has been referred to the great shipping companies for their consideration, and if it is favourably received. Application, says the

Liverpool Daily Post, will be made to Parliament for the necessary powers. The necessity for being abreast of the times has induced the Mersey Docks Board to make further improvements. The board are now engaged in rendering the Huskisson Dock available for large liners, and a third branch of the dock is approaching completion, having an entrance from the Sandon Basin, where the Mersey is 70ft. deep at low water, and where there is no natural obstruction to the ingress and egress of ships of the greatest burden.

A further meeting has been held at Bristol with reference to the proposal alluded to last week. The Bristol Docks Board had a four hours' sitting on Monday to further consider the scheme. The docks engineer, Mr. M'Currah, reported on the proposed new lock and dock, and proposed that the lock should be made 10ft. deeper than originally proposed, and that, to provide for the continual extension in the length of large vessels, the length of the lock should be increased to 800ft. The board have approved the engineer's additional report. It is evident that business is intended at Bristol.

It is fortunate that accidents of a kind like that which recently happened on the Furness Railway are not of common occurrence. The sudden disappearance of a locomotive into the bowels of the earth is not an incident calculated to inspire railway travellers with confidence, albeit that there is a spice of the humorous plainly discernible. And to say the least, it is waste of a good engine. The cavity into which the locomotive fell must have been very extensive. When 300 waggons of ballast had been cast into the hole, little progress had been made towards filling the gaping void. Early in the week, however, it was reported that the chasm had been filled in and the lines relaid, and that there was no vibration when heavy goods and mineral trains were run over the place. Nevertheless passengers wisely continued to walk over the spot—a distance of sixty yards—from one train to another, and will continue to do so until an inspection has been made by the Board of Trade. A shaft is being sunk to test the nature of the foundations of the embankment, and it is to be hoped that this will throw some light on a very singular affair.

The leaning Tower at Saragossa, though not having the popular reputation that the Pisa example enjoys, has yet been a wonder for centuries. The Torre Nueva has stood in the Plaza San Felipe some three hundred and eighty eight years, and formed one of the "lions" of the town. It is reported that the tower is to be destroyed, and that the work is even now commenced. In the year 1860 extensive works were undertaken with a view of arresting any further departure from the perpendicular, it being thought that the maximum of safe inclination had been reached. Lately, in spite of optimistic beliefs, the inclination has been observed to have increased, and with a view of safety the destruction of the building has been ordered. As in the case of the tower at Pisa, it has been conclusively established that the inclination of the Torre Nueva, at Saragossa, has arisen simply from faulty foundations. The building has served as a clock-tower, and is 70ft. high.

Mr. Loftus Brock's letter will have been perused with much interest by those who heard of the discoveries at East Langdon church. The church at Whitwell must be well worth a visit. I am not surprised to hear of interesting things architectural in East Kent. The district is not commonly visited by architects, yet between Dover and Canterbury there are many places and buildings worth seeing, and this district is, moreover, remarkable as the true home of the cut-brick "Kentish" gable.

Here is a step in the right direction. The Urban Sanitary Authority at Stockton-on-Tees, in advertising for tenders for a large new fever hospital, specified that the plumbers' and sanitary work and the heating of the premises should be let as separate contracts. This is as it should be—bringing the plumbers directly into contact with the principal employers, instead of giving them all the risk and worry of being sub-contractors. I see also that the corporation of Stockton, in

order to assist in securing good workmanship, have made it a stipulation that all the workmen employed on their works shall be paid the full rate of wages. GOTH.

CHIPS.

A new carved organ gallery has just been placed in Christ Church, Bristol. The front is divided by pilasters into a series of seven panels, appropriate subjects being depicted in five, and the end panels being filled with representations of musical instruments. In the base are cherubim, and the cornice is arcaded. Mr. George Haughton, of Bristol, is the sculptor.

The baptistry of Addiscombe Church has received an addition to its stained glass of two windows from the studio of Mr. Taylor, of Berners-street, with the subjects of SS. Mark and Luke.

New banking premises are about to be erected at New Barnet for the London and South-Western Bank. Messrs. Truefitt, of Bloomsbury-square, are the architects, and the contract has been taken at £3,800 by Mr. T. Butcher.

At the last meeting of the City of London Union a report was received from a committee as to the charges made by Mr. Barnett, surveyor for valuations for the assessment of public companies. It appeared that the total amount was £3,268 2s. 6d., and the charges were in accordance with the agreement made between the guardians and Mr. Barnett. Of this £1,800 had been paid on account, and the committee recommended that a cheque for £1,468 2s. 6d. should be drawn for payment of the balance. Some discussion took place, in which Mr. Day said Mr. Barnett was the strongest man the board could have obtained to fight on their behalf; and although the total sum was a large one, it was an excellent investment, for the increase in the companies' assessments was £133,640. The report was adopted.

The first annual excursion of the Cardiff and District Timber and Building Material Trades' representatives took place on Monday week, the place selected for the outing being Speech House, Forest of Dean. Mr. Owen Davies was the president.

New banking premises have just been built at Dulwich for the London and South-Western Bank. The upper floors are furnished as residential chambers for the manager. Mr. Charles Barry, F.S.A., is the architect, and the builders were Messrs. Smith and Son, Station Works, South Norwood. The new bank was opened on Monday.

The memorial stone of the new church of St. Paul, Walsall, was laid on the 19th inst. The church will replace one built in 1826, and will cost £9,000. It will be built of Codsall stone, and will seat 900 persons. Mr. J. L. Pearson, R.A., is the architect.

A temporary iron Roman Catholic church, seating 500 persons, was dedicated to St. Charles at Aigburth-road, St. Michael's Hamlet, Liverpool, on Sunday. The builders were Messrs. Humphrey, of Knightsbridge.

The Public Health Committee of Aberdeen Town Council have resolved to proceed with the carrying out of extensions at the City Hospital at a cost of about £12,700.

The death is announced of Albert Wolff, a sculptor much esteemed in Germany, who has died in Berlin in his 79th year. A pupil of Rauch, he is the author of numerous groups, monuments, and statues, both ideal and iconic, in Berlin, Hanover, Posen, Königsberg, and other German cities. In Berlin the work by which he is best known is the colossal bronze showing a naked rider attacked by a lion, which flanks one side of the great flight of steps leading to the Museum.

Mr. Alfred East's oil painting "Hayle from Lelant," hung at this year's Academy, has been purchased for the Birmingham permanent collection, and has just been hung in the Round Gallery in that city.

The collection of British, Roman, and Saxon remains excavated in Dorsetshire, and lately belonging to Mr. Durden, of Blandford, has been acquired for the British Museum, and will probably be on view about a month hence. Meanwhile a few specimens of cinerary urns, forming part of the collection, are to be seen in the Prehistoric Gallery. The most recent addition to the Ethnographical Gallery is the collection formed by Mr. Theodore Bent in Mashona-land, and presented by him to the Museum.

A memoir of the late Professor of Modern History at Oxford, Mr. E. A. Freeman, is about to be undertaken. Friends who may be willing to supply letters, reminiscences, or other biographical material are invited to forward them as early as possible to the Rev. Prebendary Stephens (Woolbeding Rectory, Midhurst, Sussex), who, at the request of Mr. Freeman's family, has undertaken to edit the work.

PUBLIC BATHS AND WASH-HOUSES.

—III.

By R. OWEN ALLSOP, Architect.

Author of "The Turkish Bath," and "The Hydropathic Establishment and its Baths."

IN the first article of this series the extent of the bathing accommodation required by the Act was stated as under:—

1. Vapour-baths.
2. Warm slipper-baths.
3. Cold slipper-baths.
4. Swimming-baths.
5. Cold shower-baths.

To this should be added (6) warm shower-baths. These are the baths for which arrangements must be made.

Vapour-baths have, in the past, been supplied by the old-fashioned vapour-box; but it is only here and there that we find even this simple sutory expedient provided. In many establishments the vapour-bath is entirely ignored. Yet in the schedule attached to the amendment of the Act dated July 2, 1847, vapour-baths are specifically mentioned, and the charge fixed at a similar rate to that for warm baths.

It will thus be seen that, in the majority of instances, the public baths of this country afford no means of sudation to the bathers who frequent them. In most of the public baths of Germany we find complete hot-air and vapour baths provided. Pending the general introduction of the Turkish bath in the public bath-houses of this country, it should be the least endeavour of baths commissioners to provide the ordinary vapour-box in as complete a manner as possible. It should be placed in a room or chamber fitted with warm and cold sprays, so that after the sweating process the bather may have the necessary cleansing and toning warm and cold effusions.

Every department should possess a vapour-box in default of any more complete sutory appliances. Both first and second-class bathers should have a bath of this kind available for their use. The Act expressly allows this, and consequently it is the duty of commissioners to see that such baths are provided. No great amount of space is required; an area equal to less than two of the private bath inclosures would suffice. The room should be lined throughout with glazed ware, and have a drained, tiled floor; the vapour-box, properly connected with the steam supply, would stand in one corner, and on another side of the room would be appliances for giving warm and cold sprays. Two dressing-places should be connected with the room, which, in effect, would be a kind of douche-room. Nothing in such an arrangement would be overstepping the bounds of the Act of Parliament, but the carrying out of the idea would only be properly construing its stipulations, which, as it is, are so frequently ignored.

Altogether the arrangements for any baths, except swimming and slipper baths, hitherto made in our public bathing establishments are of a very rough-and-ready and "hugger-mugger" description. Fine swimming-baths are provided, and the slipper bath arrangements are usually complete; but should the bather have a mind for a vapour bath or a hot or cold shower, the only preparations made—and that only in a few out of the many bath-houses—are of the most meagre description. There is the shower, truly, but it is only a rose inconveniently fixed above a slipper bath; and here, perhaps, is the vapour-box, but so cramped up in the narrow space of an ordinary slipper bath-room that it cannot be effectively worked.

All points to the need for a proper douche-room in the public bath-house—a chamber where the vapour-box may be placed and good shower-baths fixed.* It is impossible to study the Baths and Washhouses Act and its amendments without feeling that the present accommodation afforded in the average establishment is not in the true spirit of the Act. Swimming-baths are made much of by commissioners; but as a matter of fact it was not until an amendment of a date as late as 1878 that provision was made for swimming-baths; while less than a year after the passing of the original act, warm and cold shower-baths and vapour-baths were added to the original schedule of prices of ordinary warm and cold baths.

It may be that it has been found that vapour-baths are not in any great demand in public bath-houses. To this I would reply, that if sutory baths were more complete and attrac-

tive they would surely become more popular. It is something of a duty on the part of the State to educate the poor in this matter. It is quite comprehensible that the vapour-bath is not so popular as the hot-air bath. The former is far inferior as a bathing appliance, and the latter is infinitely more pleasant. Every experience of the past has shown that the hot-air bath provided cheaply for the people rapidly becomes popular; but the hot-air bath is not permitted by the Act, and therefore, though a poor substitute, I plead for the only sudorific expedient included therein—viz., the vapour-bath.

SLIPPER-BATHS

are the great mainstay of public bath-houses, after the swimming-baths. Indeed, during the winter they are their chief concern, the cold weather deterring the majority of swimmers. It being a popular idea that to bath properly one must soak like a potato in a complete immersion of hot water, the slipper-bath maintains its hold on the people in spite of the fact that a hot-air chamber and a pint or two of water, with soap to match, affords a more effective method of cleansing the body. The slipper-bath and its dressing chamber, apparently, is an institution that has long reached perfection; for the baths of the first days of the Baths and Washhouses Act are practically the baths of the institutions of to-day. The chief difference to be noticed in modern bath-houses is the substitution of heavy porcelain baths for the earlier and objectionable zinc troughs. The generally approved method of placing slipper-baths on the plan is in two rows on either side of a hall and with a central gangway, off which open the doors. (See plan given in Article II. published Aug. 26.) The partitions are ordinarily made of enamelled slate, the doors generally of the same material, and neither carried up higher than about 6ft. or 7ft. Economy of space is usually all-important, or half-brick, glazed-both-face walls, in cement, would make more pleasant-looking divisions than the monotonous slate. Wood is bad, the vapour and water soon destroying such partitions. For this reason the slate doors answer well although heavy, and hence liable to chip if "banged."

A cheerful waiting-room at the entering end of slipper-baths should always be provided, and proper conveniences connected therewith.

The dimensions and arrangements of the slipper baths, their dressing places, and even of the halls wherein they are placed, have become crystallised. There is a gangway, or corridor, varying in width from 3ft. to 4ft., and each bath-room measures 6ft. 6in. by 6ft. 6in., or thereabouts, the divisions being 6ft. 6in. high, and the doors the same height and 2ft. 3in. wide. The slate partitions are best held in light channel iron, screwed, bolted and bent, or forged, as may be necessary to form the requisite connections. The baths, of porcelain, should be placed, where possible, in pairs, with the partition between, so that plumbing may be concentrated. A wooden top is generally provided. Nothing beats white deal as ordinarily employed, unless it be teak, as fixed at St. George's Baths, Buckingham Palace-road. A permanent wooden seat to match should be provided. A matter of the greatest importance in connection with slipper-bath arrangements is the valves and wastes. It is evidently desirable that these should be as effective as possible—viz., that the bath should be quickly filled and quickly emptied, otherwise the attendant's time is wasted. I understand that a good valve of this class is still a desideratum, but these matters will be dealt with in their proper place.

As regards the universal adoption of porcelain baths they do not satisfy all superintendents. I have been told that the cold porcelain cooling the hot water when turned in, the bathers complain that they do not have their baths hot enough. Much the same drawback was once pointed out to me at an inland spa, where at the public bathing establishment a bathman complained that the cold, thick porcelain cooled the water, and felt cold to the bather, as a remedy for which defect he suggested a coil of hot-water pipes round the bath under the wooden top. There is a good deal in the objection to porcelain. The discomfort of being in warm water in a cold

marble bath is well known. Wood, as a top for baths, has also been criticised, the wet wood being objectionable to fresh bathers. For the two evils the remedies are curiously reverse. More business will keep the porcelain bath warm, and less to do will give the wooden top a chance of drying.

Elsewhere I have said "one other point in public baths I would mark for improvement, and that is the introduction of a cold shower bath over every warm bath—over the cheapest bath—and at no increased charge. At present we find in the slipper bath department of public baths, that one or two of the bath-rooms are fitted with the old-fashioned shower bath. Now . . . after a hot bath—unless the bather can step from the bath to his bed—the relaxed condition of the skin and perspiratory glands absolutely demand the tonic application of cold water in order that the cuticle may be strengthened and hardened

against cold. Every warm bath, therefore, should have its cold shower. The arrangement need not be anything but the simplest, and a system of waste-prevention would do away with the reckless use of water. The warm bath at present afforded by the Act in public bath-houses is a half-measure. The whole would be complete if a cold shower were appended."

This is an important point. Numberless colds must have been given and daily gained through persons going from a hot bath reeking in perspiration to the chilly air of the streets. Cases have come under my personal observation. I would, then, have this cold shower introduced over every warm slipper bath, in addition to the showers in a douche-room such as has been advocated above.

The hall or apartment in which slipper baths are placed necessarily requires abundant ventilation, there being much vapour arising from the use of the baths. A section of roof such as that shown in the accompanying illustration is to be recommended.

OBITUARY.

WE regret to announce the death of Mr. William Sugden, principal of the firm of Sugden and Son, architects, Leek. Mr. Sugden was born on June 16th, 1821, and was, there

* For plans and description of douche-rooms, see "The Hydropathic Establishment and its Baths."

* I find that there is a decided consensus of opinion among bath superintendents in favour of slate. It has been suggested to me, however, that if 3in. clear were left between slate doors and frames, there would not be a tendency to chip at the edges. Some doors fit too closely.

fore, in his 72nd year. He was a pupil of the late Samuel Frier, of Framlingham, Suffolk, and afterwards of the late Christopher Davy, of Furnival's Inn, E.C. He enjoyed an extensive practice in Leek and throughout North Staffordshire, his works in the town in which he practised including the Congregational, Wesleyan, and Roman Catholic chapels and schools, the cemetery buildings, savings-bank, mechanics' institute, and museum. He had carried out some church restorations, and many chapels and schools and mansions, in Staffordshire, Lancashire, and Yorkshire. He died on Saturday, and was buried at Leek on Tuesday last.

Mr. Matt Wyatt, eldest son of the late Thomas Henry Wyatt, P.R.I.B.A., of Great Russell-street, Bloomsbury, died on Monday at Weston Patrick, Hants. Mr. Wyatt was trained in his father's office, and for many years carried on the practice with his father, and since his death, but retired from the profession some years since. He was 52 years of age.

The death is announced from New York of Mr. Henry Hudson Holly, architect, of that city, who seems never to have recovered entirely from the effects of the accident which happened to him three years ago. Mr. Holly was, says a Transatlantic contemporary, an old New Yorker, of very good family, cultivated, agreeable, and devoted to his profession. It was his fancy, however, to carry on a rather quiet practice. His clever and useful books on "Country Seats" and "Church Architecture," which were very popular, brought him a great deal of work to be done by correspondence; but he superintended his more important buildings. He was one of the first members of the American Institute of Architects, and always ready to serve on committees, or to be of use to the profession in any way, and his courtesy and tact made him always valuable. Among his principal buildings are the Virginia Military Institute, and a house in Colorado, which is said to have cost 400,000dols.

M. Joly, the distinguished Parisian architect, who designed the Chamber of Deputies and many other important buildings in that city, died on Wednesday at the age of 68.

Mr. Josiah Dimmock, who was for many years the head of the large firm of J. and T. Dimmock and Co., English and foreign timber merchants, Stoke-on-Trent and Stone, died on Friday evening at his residence at Fradswell Hall, near Stafford, where he resided for a quarter of a century. Mr. Dimmock had been a member of the Stoke Board of Guardians from 1847 down to last year, and was chairman of the board during the last twenty-four years of his connection with it. In 1869 he was placed on the commission of the peace for the county, and thenceforward took a great interest in the business of quarter sessions. He particularly identified himself with the management of Werrington Industrial School, and was for many years, up to the time of his decease, chairman of the managing committee of that institution. On the formation of the Staffordshire County Council he contested one of the divisions of Stoke against Mr. J. F. Campbell, the head of Minton's (Limited), but was beaten. He was, however, soon afterwards elected an alderman of the council, and held that office until his death.

Mr. Thomas Gilchrist, J.P., Dean of Guild of Coatbridge, and the first senior magistrate of the burgh, died after a prolonged illness on Sunday. The deceased, who was a native of Lanark, was one of the leading builders in the district, and his practical knowledge rendered him a valuable acquisition to the town council and school board, of both of which he was a prominent member.

At a meeting on Tuesday of the Gloucester City Council it was reported that the Midland Railway Company's engineer was engaged on plans for a new station.

The Mayor of Lincoln will preside over a public meeting to be held in the town hall, Lincoln, to-day (Friday), to open the plumbing classes held in connection with the Lincoln School of Science and Art. The meeting will be under the auspices of the Lincolnshire District Council for the National Registration of Plumbers. Addresses will be delivered by the Lord Bishop of Lincoln, the Reverend the Sub-Dean, Dr. Mansel Symonds, W. Watkins, F.R.I.B.A., ex-mayor of Lincoln, and others, on the importance of the proper training of plumbers, and the promotion of improved sanitation in the interests of the public generally.

Building Intelligence.

BATH.—At Tuesday's meeting of the city council a report was presented recommending the acceptance of the tender of Messrs. Hayward and Wooster, of Bath, for £22,253—the lowest of twelve, the next being that of Messrs. J. Long and Long, also of Bath, which was only £20 more. The report also reiterated the opinion the committee had already expressed as to the advisability of further altering the plans in the direction of setting the new south wing further back. This matter has been the subject of considerable agitation in the city, and already a memorial against any encroachment on the highway had been presented. A large number of citizens now came up with another memorial that set forth that to build as projected will cause congestion of traffic by narrowing the roadway, and restrict the view of the Abbey Church. The report traversed these arguments, and said that to alter the plans would necessitate entirely new places both for the interior and exterior of the buildings, or else seriously diminish the accommodation. The spokesmen of the deputation were Mr. Titley and Mr. C. B. Oliver, the latter one of the architects who competed; and Ald. Murch, on behalf of the committee, upheld its views, and protested against the question being reopened at this stage, when no new circumstances had transpired, when the property has been purchased and tenders accepted. In the course of the discussion, numerous questions were asked of the architect, Mr. Brydon, who was present, and the tendency of his replies was that to alter the site as suggested would increase the difficulties of providing the accommodation required. By a majority of three, 24 to 21, the report was sent back to the committee, with the object of amending the plans.

CARMARTHEN.—A new school of art is in course of erection facing St. Peter's Church, Church-lane, at a cost of £1,500. It is Modern Renaissance in character, and is built of red Bridgwater bricks, the mouldings and cornices being of Ruabon bricks, and the dressings of Bath stone. Accommodation is provided for 70 pupils. Entering through a hall, laid with tessellated tiles and divided by an arcade supported by fluted and moulded pilasters, one finds on the ground floor an elementary-room 37ft. by 20ft., and a modelling-room 18ft. 6in. by 19ft. The rooms are 16ft. high. The upper floor contains a room 37ft. by 20ft., and a master's room 18ft. by 12ft. The former will be divided by a curtain or movable partition, and the divisions will be used as painting and antique room respectively. On the upper floor there are also lavatories and a ladies' cloak-room. The work has been carried out by contract by Mr. T. Morris, Carmarthen, from the designs and under the superintendence of Messrs. G. Morgan and Son, architects, of that town.

DUBLIN.—The old front of the City of Dublin Hospital in Bagot-street has been removed for the purpose of reconstructing and enlarging the premises. The plain red brick edifice will give place to a building of a more modern character. The alterations when completed will result in more accommodation being provided for the patients; the institution will have more beds at disposal, and additional room will be afforded for the nursing staff. New quarters are being erected for the resident pupils, and the house-surgeon will have a room to himself. The work of improving the building has been rendered possible by the gift of £6,000 from Earl Pembroke, who also recently presented a large sum of money for the establishment of technical schools at Ringsend. The architect is Mr. E. Murray, and the contract is being carried out by Mr. Samuel Worthington, also of Dublin.

EDINBURGH.—The Grange Cricket Club are about to erect a new pavilion on their ground at Raeburn-place, at a cost of nearly £3,000, which promises to be one of the most ambitious affairs of its kind in Scotland. Designed in the Domestic English style—the lower story being constructed of stone and the upper portion of brickwork, faced with cement and open timber work—the main building will occupy a site immediately behind the existing structure, and will measure 58ft. 6in. by 48ft., irrespective of a sloping grand stand, which will project about 40ft. forward, and seat about 250 persons. On the ground floor will be a dressing-room measuring 40ft. by 20ft., a professionals' dress-

ing-room, a bedroom, parlour, and kitchen for the caretaker, and lavatory accommodation. Under the grand stand, nets, rollers, and other appliances for the game will be housed. Entrance to the upper or main floor can be had either by an inside stair, or by the inclined gangway which runs up the centre of the grand stand. The pavilion hall, which has an open timber roof, will measure 56ft. by 27ft. 6in. On one side will be a committee-room, and on the other a dressing-room. On the roof there will be sitting accommodation for 200 people, the access to this being obtained from a square tower, the pinnacle of which will be 60ft. high. The roof of the tower and of the main building, so far as not set apart for sitting accommodation, will be treated in red tiles. The architects are Messrs. Cunningham, Blyth, and Westland, George-street, Edinburgh.

HEREFORD.—For some two months past a staff of workmen have been engaged in the extensive work of re-fitting, re-painting, and renovating the premises of the National Provincial Bank of England, Broad-street. The heavy counter has been removed, and also the old-fashioned boxes in the centre of the large hall, giving freedom of ventilation and increased comfort, the old furniture being replaced throughout with French-polished mahogany fittings. Along the front of the counter a new wrought-iron "grill" of novel design has been placed with massive gas standards of brass at intervals. New lavatory arrangements have been carried out in the basement, the lavatories being lined with white glazed bricks. The whole of the work has been carried out under the direction of the architect, Mr. Charles R. Gribble, of London, and Mr. Grimes, the clerk of the works. Messrs. W. P. Lewis and Co., Commercial-road, Hereford, carried out the contract.

NEWPORT, MON.—The new church of St. Matthew, Church-road, Barnardstown, was opened on Monday. The building has been erected by Mr. Charles Lock from designs prepared by Messrs. Graham, Son, and Hitchcock, and is in a plain Gothic style. It is built of random rock-faced Pennant stone-walling, and Bath-stone dressings. The roof is of open timber and match-board, covered with slates. The building will seat 512 persons easily, but in an emergency 600 can be accommodated. The internal walls are stuccoed, and the woodwork is stained and varnished. The whole of the interior is one open space, so that an uninterrupted view of the clergy can be given to the congregation. There is a transept on either side, and a choir vestry and organ chamber. Provision has also been made for heating the building. The cost has been £3,300.

READING.—On the invitation of Mr. Slingsby Stallwood, architect (chairman of the Survey Committee), members of the corporation and others, on Thursday in last week, inspected the works of reconstruction at the Hospitium in St. Lawrence's churchyard (which has been adapted for the use of the Extension College and School of Science), and the Corn Exchange, which has also lately been completely renovated. Assembled in the lecture hall, Mr. Stallwood sketched the history of the buildings, which originally formed part of a dormitory attached to St. John's Hospital, erected by Abbot Hugh in 1192. They consist of a fine lecture-hall and a class-room, two sets of lavatories and cloak-rooms, on the lower floor, with communication from the churchyard and from Valpy-street; on the next floor a good room used as a council room by the college authorities; and on the top floor a laboratory with bench accommodation for 32 students, a room for the science master, a balance room, and a small theatre. The work has been carried out under the direction of the borough surveyor (Mr. A. E. Collins), with Mr. George as clerk of the works; Mr. Stallwood supervising the preservation and restoration of all the ancient features.

A steam saw mill at Warminster, belonging to Mr. Mark Hill, was destroyed by fire on Friday. The damage is estimated at over £2,000.

After being closed for six months pending alterations, the parish church of Blackford, N.B., was reopened on Sunday last. A chancel 20ft. deep has been added, completing the cruciform design of the church. At the same time the heating and lighting apparatus have been renewed and enlarged, the old windows changed for others of tinted glass in lead frames, and the interior repainted.

Engineering Notes.

BRISTOL.—The Bristol Docks board had a four hours' sitting on Monday, to further consider their scheme for dock extension at Avonmouth, which is to cost over a million of money, the scheme being put forward to attract Atlantic liners to the port. The Docks engineer, Mr. M'Curich, reported on the proposed new lock and dock, pointing out that as he found from borings taken at Avonmouth, that the rock would allow of the proposed locks being made ten feet deeper than originally proposed, he suggested that this extra depth be obtained. He also proposed that the lock should be increased to a length of eight hundred feet, and that additional land be taken in order to make the dock of sufficient extent to allow for the accommodation of a larger class of vessels. The estimated cost of this work, including the deepening of the channel, was about £50,000. The Board approved the engineer's additional report, and the Town Council have also adopted it.

MARTON AND LEAMINGTON RAILWAY.—The new line from Daventry to Leamington, in connection with the main line of the London and North Western Railway from London to Birmingham, was commenced by a large staff of men and a plentitude of material at Daventry on Tuesday, the 13th inst., and when completed, it will lessen the distance between London and Leamington by 8½ miles. The distance to be traversed will be a total of 26 miles, being 11 miles from Daventry to Marton, and 15 miles from Daventry to Leamington, and it is anticipated that the line will be completed in two years.

ARCHÆOLOGICAL.

WENHASTON.—During the restoration of the parish church of Wenhaston, East Suffolk, a work just commenced by Messrs. Ludkin and Son, of Banham, under the direction of Mr. E. F. Bisshopp, F.R.I.B.A., of Ipswich, a painting on oak boards of "The Last Judgment" has been found covered with whitewash and plaster. It appears to have formed the upper part of the chancel screen, and is nearly perfect. The picture, which measures 16ft. by 8ft. 6in., was subdivided into panels by a wooden cross fastened on with bolts, of which only the holes now remain, and the two bottom side-panels were apparently formed by the carved images of patron saints which have also disappeared. The top panel represents our Lord coming to Judgment on clouds supported by a rainbow, the companion panel being devoted to the Virgin and Joseph, both being in a kneeling posture. Beneath our Lord is a group consisting of a figure of St. Peter in pontifical robes and four nude figures wearing crown, mitre, cardinal's hat, and coronet. The companion panel shows St. Michael with sword, and a winged devil with horns, hoof, and tail, between them a scales with a nude human figure in the left balance outweighing two imps in the right scale. To the right is a panel portraying an open-mouthed dragon's head, containing nine nude human figures inclosed by two demons with a red-hot chain, one of the demons holding in his hand a rake.

CHIPS.

Mr. Charles Mitchell, of Elswick Works, has offered to contribute from £10,000 to £12,000 towards the extension of Aberdeen University, on condition that science classes for artisans are established in the evenings; that professors of engineering and agriculture are appointed; and that a large central hall is included in the plan for the enlargement of the present buildings.

On Saturday was opened the Beveridge Park, at Kirkcaldy. The park extends to 110 acres, and formerly formed part of the estate of Raith. It lies at the west end of the burgh, and commands a splendid view of the Firth of Forth and surrounding country. The band-stand was erected by Messrs. M'Donald and Stevens, Glasgow.

The first annual scholarship of the Royal Drawing Society has been awarded to Miss F. M. Price, of the Southsea High School.

The presidency of the Junior Engineering Society for the ensuing session has been accepted by Dr. John Hopkinson, in succession to Sir E. J. Reed. The new session will be opened by the delivery of Dr. Hopkinson's presidential address on Friday, Nov. 4, at the Westminster Palace Hotel.

COMPETITIONS.

CLERKENWELL POLYTECHNIC.—Mr. Charles Barry, F.S.A., has been appointed assessor in this competition. The building is to cost £100,000, and several architects have been invited to compete.

SALFORD.—The Salford School Board have chosen Messrs. Woodhouse and Willoughby, architects and surveyors, of Manchester and Stockport, to design the St. Margaret's School for 500 scholars. The estimated cost is £4,651. At the same meeting of the board, held on Monday, Mr. Henry Lord, of Manchester, was appointed architect of the schools at Ordsel, which will accommodate 340 children at an anticipated outlay of £3,120. The names of eight firms were chosen by the board from which to make their selection.

LLANELLY.—This town hall competition has been settled in favour of Mr. W. Griffiths, F.S.I., of Llanelly, who was placed second by the referee, Mr. Charles Barry. The first premium was awarded to Messrs. Frank W. Simon and Tweedie, of Edinburgh and Manchester. These gentlemen warmly complain very naturally that the assessor's award should have been thus ignored by not appointing them architects for the work, and the merits of the designs no doubt justify their complaint, besides which, having obtained plans on the assurance that a competent assessor would be appointed to select the designs, the promoters were morally bound to consider the condition binding on all parties. Mr. Griffiths offered, we understand, to undertake the work at four per cent.; while the other architects seemed to have asked the usual five per cent. commission. This is a free country, and if people like to work for nothing, there is no law to prevent it. No doubt some men would undertake work for half the price usually paid; how it would be done is another matter. Open competitions always present the difficulty of distance. Travelling to and from Llanelly to Edinburgh constantly must be an expensive affair, and time consumed in travelling soon runs into money. A man on the spot always, therefore, competes with advantages in this respect—particularly in Wales.

VICTORIA CATHEDRAL, B.C.—The competition held in London last May, when we described and illustrated the best designs submitted, has now been settled, and Messrs. Keith and Evers, of Victoria, are the elected architects for the work. Their plan was a fairly good one, and had a central western tower and spire, the church being conceived in an Early English style; but the design was commonplace, and hardly competed seriously with the two other premiated designs, "Ars" and "New and Old"; though, no doubt, the latter was quite unsuitable for execution in Vancouver and on such a site. Sir Arthur Blomfield, A.R.A., was the referee, but as his report cannot be obtained, we can only quote the words of the Hon. Sec., who writes us that "Fides" "appears to have been considered the most appropriate by Sir Arthur Blomfield." As far as we were able to form an opinion on the merits of the designs, there seemed no question that "Ars" was out and away the most appropriate design, and the recommendation of the referee as above communicated seems inexplicable, so that we can hardly think our informant can have been correctly advised by the Bishop of British Columbia. Messrs. Keith and Evers "have been called upon to show by tenders that the work can be done for the money." This probably will tax their ingenuity, as the elevations were busy with big rose windows full of tracery, and this kind of work in British Columbia is expensive, and difficult to get well executed. The author of "Ars" is, we believe, Mr. A. R. Scott, of Westminster, from Paisley, N.B.; and the gentleman who sent in the design marked "New and Old" is, we are told, Mr. H. Wilson, of the late Mr. Sedding's office. Both these designs are to receive premiums—one £100, and the other £50. The order in which they stand is uncertain. Messrs. Keith and Evers are to be paid the £150 prize.

Messrs. Baird, Thompson, and Co., ventilating engineers, of London and Glasgow, have been commissioned by one of the principal firms of Atlantic steamship owners, who have practically experimented and tested that firm's improved patent combined system of mechanical and automatic ventilation as applied to one of their ships, under the guarantee of no cure, no pay, to fit up all their fleet of ships with the same.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. All communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondents.]

It is particularly requested that all drawings and all communications respecting illustrations or literary matter should be addressed to the EDITOR of the BUILDING NEWS, 332, Strand, W.C., and not to members of the staff by name. Delay is not unfrequently otherwise caused. All drawings and other communications are sent at contributors' risks, and the Editor will not undertake to pay for, or be liable for, unsought contributions.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

TERMS OF SUBSCRIPTION.

One Pound per annum (post free) to any part of the United Kingdom; for Canada, Nova Scotia, and the United States, £1 6s. 0d. (or 6dols. 30c. gold). To France or Belgium, £1 6s. 0d. (or 33fr. 30c.) To India, £1 6s. 0d. To any of the Australian Colonies or New Zealand, to the Cape, the West India, or Natal, £1 6s. 0d.

ADVERTISEMENT CHARGES.

The charge for Competition and Contract Advertisements, Public Companies, and all official advertisements is 1s. per line of Eight words, the first line counting as two the minimum charge being 5s. for four lines.

The charge for Auctions, Land Sales, and Miscellaneous and Trade Advertisements (except Situation advertisements) is 6d. per line of eight words (the first line counting as two), the minimum charge being 4s. 6d. for 40 words. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph Advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Vacant" or "Situations Wanted" is ONE SHILLING for TWENTY-FOUR WORDS, and Sixpence for every eight words after. All Situation Advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 3 p.m. on Thursday. Front-page advertisements and alterations in serial advertisements must reach the office by Tuesday Morning to secure insertion.

NOTICE.

Bound volumes should be ordered early (price Twelve Shillings each), as only a limited number are done up. A few bound volumes of Vols. XL, XLII, XLVI, XLIX, L, LI, LIII, LIV, LVIII, LIX, LX, LXI, LXII, and LXIII may still be had, price Twelve Shillings; all the other bound volumes are out of print. Most of the back numbers of former volumes are, however, to be had singly. Subscribers requiring any back numbers to complete volume just ended should order at once, as many of them soon run out of print.

RECEIVED.—F.R.I.B.A.—G. B. and Co.—S. Australian.—L. R. and M. F. Co.—B. J. M. (Dublin).—T. W.

Correspondence.

THEATRES.

To the Editor of the BUILDING NEWS.

SIR,—Mr. Woodrow, in his Article No. V. (BUILDING NEWS, Aug. 19), has dealt with one of the most interesting, and, as he admits, one of the least understood, requirements of theatre building. He is, however, of the opinion that by the observance of "certain fundamental rules" as to "proportion and the employment of suitable materials" a building may be produced in which it will be "easy to hear in, speak in, and sing in." Herein lies the crux of the whole question. What are the proportions and materials most favourable to the acquisition of acoustic excellence in a theatre? Mr. Woodrow's answer is somewhat of a negative one. He deprecates the use of wood, seemingly on the ground that the advocates of this material in the past had no knowledge or experience of the resonant qualities of concrete and iron as constructive materials. It does not necessarily follow that because a material is resonant it is therefore the best to use in the construction of a theatre. From my own observations, I am of opinion that acoustic perfection is a matter not easy of attainment in fire-proof theatres, where the exigencies of concerted music and oral delivery have to be equally provided for. As I pointed out in a communication to the BUILDING NEWS, March 16, 1888, such a combination of desirable conditions are not easy of attainment, in so far that certain acoustic properties favourable to musical performances are inimical to the propagation of oral sounds. Mr. Woodrow implies that there is "little difficulty" in obtaining fireproof theatres of "limited size" that shall possess all the most desirable acoustical properties; but he fails to

mention a theatre where these desirable conditions are to be found. So far as the opportunities for comparison have enabled me to form an opinion, the concrete theatre does not, acoustically, compare favourably with the older theatres wherein the predominating material is wood. The mere fact that concrete is more or less resonant, and that it may be used with advantage—as I have seen asserted—for organ floors, does not prove its superiority to wood as a reinforcing medium under all and every condition.

Mr. Woodrow does not touch upon the desirability of adopted "harmonic proportions." This, I am aware, is a very abstruse subject, but assuming that "harmonious proportions" constitute one of the conditions essential to acoustic excellence, their adoption in buildings constructed with modern fireproof materials appears to be far more a necessity than in buildings constructed with wood. Wood may be said to vibrate in sympathetic responsiveness to all notes, whereas the several fireproof building materials are each more actively responsive to particular notes and sounds. To this extent, the employment of concrete as an acoustic material is merely tentative, whilst on the other hand, the results to be obtained from the use of wood can be accurately pre-determined. It has, therefore, to be yet proved to what extent the rules and conditions conformable with acoustic perfection in a building lined with wood are applicable to buildings constructed entirely with fireproof materials. I am aware that the builders of the most recent theatres claim for them acoustic qualities equal, if not superior, to those of earlier date; but it would be interesting to have the opinion of musical and dramatic professionals—who are always quick to detect the non-existence of good acoustic properties—as to the acoustic qualities of the new theatres as compared with the old. Personally, I have experienced difficulty in hearing distinctly in even the smallest of the concrete and iron theatres, and I am not alone in experiencing a similar difficulty in one of the largest. That the problem under consideration is not one of the simplest connected with theatre building is admitted by Mr. Woodrow. Fireproof material, *per se*, does not absolutely commend itself on the score of its unquestionable acoustic qualities, for in the concluding paragraph of his article he does not hesitate to award to the upholsterer, and the clothing of the audience, "an important part" in assisting "in the perfection of the acoustic qualities of a fireproof building."

Bearing upon the question of proportion, Mr. Woodrow quotes an authority who asserts "that the proper distance for distinct hearing was nearly the same in a long, narrow room or passage, as in a large square room."

This statement does not appear to be in accord with past experience and practice, for concert-rooms and lecture-halls are invariably planned with a near approach to a double square than otherwise. Experience has confirmed the theory that contracting the width of a room has a tendency to give a consequent forward impulse to sounds emanating from either end, and also to lengthen the distance at which such impulses are audible from their original source. It is further agreed by those who have carefully considered the subject, that, with the object of securing the best acoustic results, the predominating dimension of an interior should be in the direction in which the voice is intended to travel. From this it is reasonable to infer that a square-planned room is not compatible with the economical conservation of sound.—I am, &c.,

Sept. 26.

JAMES GEO. BUCKLE.

PUTTING IT PRETTY.

Sir,—The inclosed gem in the way of architectural description, is cut from to-day's *Daily Independent*. It describes a new church at Leicavay which must be worth a pilgrimage to see. The designer has, with native modesty, suppressed his name. We read that "it is of Gothic design." A cast-iron circular staircase, which is beautifully bronzed, leads to the organ gallery, which is supported by iron columns. We also find that the chancel arch of this Gothic church is supported on marble pillars with Grecian O G mouldings. Oh! for the name of the designer of such a church. Here is the description:—"The new church, which is 97ft. long by 44ft. wide, is of Gothic design, and a cut stone belfry, 54ft. in height, rises from the

front. The interior of the church is beautifully finished. The ceiling is panelled, and the principals, which are of spruce memel, rest on cut stone corbels, and are connected and supported by iron suspension rods. A cast-iron circular staircase, which is beautifully bronzed, leads to the organ gallery, which is supported by iron columns. The moulding in the front of the gallery is of walnut wood. The walls are wainscotted with pine, while the rails of the sanctuary, which are designed in accord with the Gothic style of the building, are capped with white oak. The arch of the chancel is supported on marble pillars with Grecian O G mouldings, the roof being of diagonally framed panels, with raised walnut mouldings, while the back is wainscotted in oak."—I am, &c., A DUBLIN ARCHITECT.

Intercommunication.

QUESTIONS.

[10860.]—**Mounting Drawings.**—Will some surveyor, or other person experienced in this kind of work, kindly give some information as to the proper way of mounting drawings, maps, &c., on cloth; the kind of cloth, not too thick, and the mounting medium to be used?—A. F. F.

REPLIES.

[10833.]—**Timber and its Position.**—Sidney F. Harris states that "the reason for placing staves inversely to their natural position is because the sap-valves open upwards from the root, and when thus reversed they prevent the ascent of moisture in the wood." Will your correspondent kindly inform us in what sort of wood these valves can best be seen, and how their action can be demonstrated?—E. S.

[10842.]—**Composition for Renovating Stone-work.**—Saturating the stone with Randall's solution will harden it and enable it to further resist frost; and the same mixed with plaster could be used to fill in defective places. Such plaster would also be unaffected by frosts, and the work might even be done in frosty weather without injury.—J.

[10848.]—**Books for Student Surveyors.**—"Kappa" should first get his boy to master the ordinary rudiments of arithmetic, geometry, and mensuration. The problems on triangles and other figures of planes and solids ought to be mastered. Baker's "Mensuration," "Land Surveying and Levelling," and G. W. Uaill's "Practical Surveying," all published by Crosby Lockwood, are excellent elementary books for learning these matters. If "Kappa" can get his boy to join some surveying class, such as are given in some technical schools, it would be of service by-and-by. For valuing and auctioneers' work, the practical knowledge learned at the office may be supplemented by reading such books as Tarbuck's "Handbook of House Property," "The Law of Vendors and Purchasers of Landlord and Tenant"; but these may be taken up later. The Secretary of the Surveyors' Institution, Great George-street, Westminster, will send all particulars as to the examinations on the five divisions, a syllabus of the subjects and list of text-books and papers set, by which "Kappa" may set his boy to work on the lines therein laid down. The books recommended by the Institution would be desirable to obtain, or some them.—G. H. G.

[10849.]—**Swedish Wooden Houses.**—I am not certain that a Swedish wooden house has any distinguishing advantage over other houses constructed of wood. The houses are generally built of square logs, without the projecting carved work or gables, &c., seen in those of Switzerland. Some houses have stone basements; the upper stories have lofty and large rooms; rarely with fireplaces, but heated by glazed tile stoves. By using asbestos to fill between the floor joists, and to line the walls and partitions, a fairly uninflammable house could be built. The saving effected in such constructions would be small as to comparative cost in a place where bricks are cheap. The wooden construction would be available for vestries, meeting-rooms, &c., if proper care be taken in construction.—LIGNUS.

[10850.]—**National Competition Drawings.**—The drawings in building construction sent in to these competitions are, I think, done to an inch scale. They are generally coloured in the usual tints to express stone, wood, and iron. Perspectives are optional, I believe.—GEORGIUS.

[10851.]—**Bedding Iron and Wood on Stone.**—Notwithstanding the experiments cited by "J. H.," I should be inclined to interpose a piece of sheet-lead between the iron and stone template as tending to equalise the pressure of the girder on the stone. Layers of pine would be equally desirable. The intervention of a soft material must prevent the danger of chipping, or as masons call it "flushing," and for this purpose they generally put between the stones of a column sheets of lead. It is questionable whether any such material is necessary between a heavy wood bressummer and a stone template. It would, however, be desirable that the template should be dressed perfectly level, and the extreme edge slightly bevelled to avoid a flushing taking place at the angle. A weighted beam must compress the extreme angle or nosing of the stone more than it does the inner part of the bearing.—PRACTICAL.

[10851.]—**Bedding Iron on Stone, &c.**—In bedding flat-ended columns on stone, great accuracy is required to prevent fracturing the stone on which the column rests. In specifications for this kind of work, the architect should require that the base of iron column be faced in the lathe, and that the stone be dressed perfectly level to give an even bearing. In addition to this, under heavy loads it is desirable to place a sheet of lead or felt between the base of column and stone. Another

plan is to run in liquid cement between the two surfaces after the column has been fixed quite plumb, so that all inequalities of stone and iron be filled up. This cement solidifies, and forms a hard bed. In the case of cast-iron girders resting on stone or bearing plates, it is desirable to specify that a layer of sheet-lead or felt be introduced between the surfaces, so as to distribute the pressure. The slight thickness of the impressionable lead assists to equalise the pressure, and prevents the bottom flange of girder from pressing on the edge of stone template. Fracture and chipping of the stone are thus avoided. I think that felt is quite sufficient for the purpose, especially if the bearing surfaces are large, and the pressure not very great. All abutting surfaces of stone and iron should have either lead or felt or thin laminae of pine, and this precaution is especially desirable when the surfaces are not truly faced, or are uneven.—G. H. G.

[10854.]—**Laboratories.**—The benches or working tables should be of stone or brick built up from a concrete foundation. For electrical experiments, brick pillars about 2ft. square may be constructed for the tables, these piers being taken down to the solid ground or rock.—G. H. G.

[10857.]—**Testing Drains.**—One way of testing drains is to obtain some oil of peppermint, and placing a sufficient quantity of it in some warm water, throw it down the rain-water pipe or some outside gully, closing the same immediately afterwards. Any leakage or defect in the drains will quickly be revealed if another person uncontaminated with the odour goes carefully over the house and tries to discover the smell of the peppermint. The doors and windows of the house should be closed before the oil is thrown, so that no smell of it should enter the house and vitiate the test. Perhaps some more practical drain-tester than I am may give "Sewer Gas" more definite instructions as to the manner of testing.—T.

[10859.]—**Hopton Wood Stone.**—This is a fine-grained, grey, marble-like stone, excellent for all weathering purposes, and used for steps and paving. I should think it would answer well for monumental purposes, and it takes a polish. One authority says, "it is useful for all internal and external purposes, and is a good weather-stone, including monumental work." It is hard and crystalline.—AN ARCHITECT.

CHIPS.

Messrs. John Knowles and Co., of 38, King's-road, St. Pancras, N.W., have been awarded by the judges (Mr. Rogers Field, C.E., and Mr. Baldwin Latham, C.E.) of the Health Exhibition, Portsmouth, held under the auspices of the Sanitary Institute, a certificate of merit for the patent seat action and flushing tank of the "Presto" closet exhibited by them, a full notice of which was given in our issue of June 3 last.

Mrs. Creighton has prepared a scheme for raising several thousand pounds towards the restoration of Peterborough Cathedral, through lady collectors in every parish in the diocese. It is termed a "Women's Fund for the Restoration of the Cathedral Organ and the completion of the Choir fittings." A large general committee has been formed, and £746 has already been promised.

The second excursion for 1892 of the Dundee Institute of Architecture, Science, and Art, will take place to-morrow (Saturday), when Clatto reservoir, and places of interest in the districts of Auchterhouse and Meikle will be visited. At Clatto, Mr. George S. Baxter, water engineer of Dundee, will explain the plans adopted, and also the mode of laying the pipes.

The Norman church of St. Nicholas, North Newbald, near Market Weighton, was reopened on Thursday in last week by the Archbishop of York after restoration. Rather over £400 has been spent in re-roofing the transepts and the vestry, repairing the pinnacles and parapet of the tower, and carrying out minor improvements in the interior.

A large stained-glass window has just been placed in Ingrow Church. The window illustrates the Good Shepherd, the Good Samaritan, and the Lost Piece of Silver, placed in the upper, middle, and lower spaces respectively. Each subject is surmounted by canopy work. The window is from the studio of Messrs. Powell Brothers, of 30, Park-square, Leeds.

A special meeting of the executive committee of the Swansea Harbour Trust was held on Wednesday, when Mr. Law, superintendent of the Hull Alexandra Dock and Railway, was appointed superintendent at a salary of £800 a year.

The Queen has commissioned Messrs. Matthews and Mackenzie, architects, of Aberdeen, to prepare plans for a new church to be erected on the site of the present ancient, but now almost ruinous, edifice at Crathie, in which Her Majesty has so frequently worshipped. Mr. Mackenzie has had an audience with the Queen on the subject.

Dissolution of partnership is announced in Tuesday's *London Gazette* as between Helyer and Munt, of Bournemouth, architects and surveyors.

The electric lighting of the Smithfield Markets is rapidly approaching completion. Under the contract, which is being carried out by Messrs. Julius Sax and Co., on behalf of the City Corporation, the tenants of the markets will not be put to any expense in the installation of the light upon their premises, and they will only be charged the same amount that they have been paying for gas.

Legal.

"OPEN AND UNBUILT UPON."

THESE words are often used in covenants to keep a square or garden that is surrounded by buildings in its then state as an open space, to admit of free light and air to the adjoining premises. In the recent case of "Graham v. Corporation of Newcastle-on-Tyne" (*Times*, July 24), an action was brought by the plaintiff, the owner of certain houses in Charlotte-square, Newcastle, to prevent the corporation from erecting a public urinal in the square. The covenant provided that the garden or open space in the centre of the square should "for ever thereafter be kept open and unbuilt upon." It appeared that the square was in the shape of a hill, and was supported by a high retaining wall. The defendants had begun excavating the ground, and were about to put up a public urinal in the square, with an entrance through this wall, but so built that it would, even when completed with a glazed and concrete roof, be in every part below the level of the adjoining surface. The plaintiffs now sought for an injunction to stop this being done, on the ground that it would be a breach of the covenant to keep the square "open and unbuilt upon"; and also on the further ground that a urinal so placed would be a nuisance to the surrounding houses.

Mr. Justice Kekewich first of all got rid of the word "garden" in the deed by holding that it only meant the same thing as an open plot of ground, because it was admitted that the land in question had never been used as a garden of any sort. In other words, as it had been an "open space," it was to be kept so for ever. This meant, he held, that it should be free from obstruction, and so that the air could circulate without being interfered with by any building. He considered that the words "and unbuilt upon" were simply an enlargement of the term "open," and did not carry its meaning any further. The learned judge further considered that other ground might be built upon and still remain open; and he instanced a greenhouse as a building that would not be any obstruction to light and air. Having thus whittled away most of the covenant, he then held that the building proposed to be erected by the corporation, and being practically underground, would not interfere with the space continuing to be "open" in the sense he had explained. As to its being a nuisance, that did not necessarily follow from the fact of its being a urinal, and, at all events, that question would be raised when the work was done, and evidence could be brought of the results. So the motion for an injunction was dismissed; costs to abide the result of the action. But all the same, it is pretty clear that a public urinal built in a square, however elegantly it may be sunk and roofed in, must damage the surrounding dwelling-houses as property, and must be a nuisance to the tenants. Perhaps the Court of Appeal will be asked more clearly to define the words "open and unbuilt upon."

FRED WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

SUFFOLK.—DILAPIDATIONS.—LEASE.—I answer these questions as asked; but much must depend on the age, quality, and condition of the property. 1. The landlord. 2. Landlord. 3. I think not. 4. If in a very bad state. 5. If very bad, as they were before. 6. I think not. 7. Painted.

BANBURY.—MORTGAGE STAMP.—The proper stamp on a mortgage for £100 would be 2s. 6d.; and so on upwards, according to the scale in the Stamp Act, 1891.

LEGAL INTELLIGENCE.

CHURCH RESTORATION WITHOUT A FACULTY.—Judgment has been given in the Consistory Court of Hereford refusing a confirmatory faculty for alterations made by the vicar and churchwardens of Upton Bishop, by which an Early English doorway in the chancel had been destroyed, and a vestry erected as a memorial to the late Miss F. R. Havergal materially injured, without the consent of her relatives, in order to place an organ in the chancel. The case was reported in our issue of July 1st, p. 33, present volume. Dr. Tristram now said the petitioners had committed a serious offence against ecclesiastical law, and that had restoration to its former condition been practicable, they would

have been required to effect such restoration at their own cost. The vicar was ordered to pay the costs of Messrs. Havergal, who had opposed the faculty, after objecting to the alterations.

RE F. STEVENS.—The adjourned examination of this bankrupt, a builder, of East Grinstead, took place on the 22nd inst. The debtor said he started business in East Grinstead in July, 1888, having no capital, but with £150 borrowed money. The firm was styled Pierce and Baynard, he being known as Baynard. He was also in business at Durham, Harlesden, Finchley, and other places. He took contracts, but for the last two years had made no profits. He never had any working capital, but believed his balance at the bank in 1890 was £200 or £300. He had only taken two or three contracts, on all of which he had lost money. When Head's Bank stopped in February he admitted that he had many dishonoured bills about. The Official Receiver pointed out that, as a matter of fact, in June, 1890, there was an adverse balance in the Bank against him of £816, and in September of the same year that had increased to £2,713, and afterwards to £4,894. He left this country, and went with his wife and children to America, where he stayed a year, and came back to Stamford Hill, where he was a builder's foreman. The examination was adjourned until October 13th.

BAD PLASTERING.—On the 27th September, at the Lambeth Police-court, before Mr. Biron, Q.C., Mr. Charles Watts, builder, was summoned at the instance of Mr. Ellis Marsland, district surveyor for Camberwell, for a breach of the by-laws relating to plastering at a certain house in course of erection in the Worlingham-road, East Dulwich. The surveyor produced several specimens of the plastering taken from the walls and ceilings of the building, also two analyses of the material, showing from 15 to 18 per cent. of earthy matter, and explained that the defendant had a mortar-mill, and surrounding it were heaps of all sorts of rubbish which was ground up in the mill with a small proportion of lime and hair. Whereas the by-laws provided that clean, sharp sand, without loam or earthy matter, or ground brick or furnace slag, to the satisfaction of the district surveyor, mixed with lime in the proportions of three to one, were the only materials allowed to be used, with the addition of hair. The magistrate fined the defendant £5 and 2s. costs.

WATER SUPPLY AND SANITARY MATTERS.

HIGHCLERE PARK.—The waterworks on the estate of the Earl of Carnarvon at Highclere Park, which have been in process of construction for some time, were put to a practical test on Friday afternoon, particularly as regards their efficiency in case of fire, by the Newbury Volunteer Fire Brigade. The works have been designed and carried out by Mr. Richard Ravenor, of Newbury. The pumping-station is about two miles from the reservoir, and the water-supply is obtained from springs and collected into an underground tank, and from thence into one above ground, and it is from the latter that the power for working the hydraulic ram is obtained. The ram is worked on the continuous-flow principle, and will supply the castle, stables, and flower-gardens, as well as the dairy and home farm. The reservoir, which is on Siddown Hill, is capable of holding 135,000 gallons, and its height above the ram is 400ft., and above the flagstaff tower of the castle 30ft. It is constructed of concrete, and has a flat covering of the same material. A fire main connected with this reservoir is laid completely round the exterior of the castle, and hydrants are placed so as to connect the hose in case of fire. A fire main runs up through the centre of the building inside, with hydrants on each floor, and 60ft. of hose, with branch-pipe attached to each.

MACCLESFIELD.—The corporation of Macclesfield, having been urged and threatened by the joint-committee of the Irwell and Mersey, have at last decided to undertake a main-drainage scheme, the estimated cost of which is put down at from £20,000 to £30,000. At the beginning of 1888 the corporation offered 100 guineas in competition for plans, estimates, and reports as to the carrying out of the River Pollution Act in the borough. This resulted in a number of plans being sent in, and the prize was awarded to Mr. W. H. Radford, C.E., of Nottingham, the competitive plans becoming the property of the corporation. Still the council delayed in carrying out the project, and in May of this year a deputation waited on the joint-committee of the Mersey and Irwell at the Manchester Town-hall to explain why proceedings should not be taken against the corporation in respect of their failure to deal with the sewage. The corporation said they had not been able to agree as to the best system to adopt, irrigation or precipitation, and the committee allowed them a further period of three months. In June Mr. John Newton, C.E., of Manchester, who was consulted by the sanitation

committee, recommended an irrigation scheme, which was adopted, Mr. Radford, of Nottingham, being appointed the engineer. Mr. Radford is now engaged drawing up a new plan.

NELSON, LANCS.—Water was on Friday for the first time allowed to enter the new compensation reservoir constructed at the foot of Pendle Hill, about five miles distant from Nelson. The ceremony was formally performed by the mayor of Nelson, who also formally opened the new filter beds constructed in the Ogden Valley, about a mile distant from the new reservoir. The beds and the reservoir have been designed by Mr. John Newton, engineer, of Manchester, and have been constructed by Messrs. Etheridge, Clark, and Co. The reservoir, which has a holding capacity of 40,000,000 gallons, was commenced about 18 months ago. It impounds the Black Moss stream, and is the first of a series of reservoirs to be constructed by the corporation of Nelson under the authority of an Act obtained four years ago. The filter beds are two in number, and are constructed in the Ogden Valley at an elevation of 900ft. above the sea level. They have each a holding capacity of 700,000 gallons, and by a 10in. main leading into them from the Ogden stream 600,000 gallons (equal to about a day's consumption in Nelson, Brierfield, and Barrowford, all of which places come within the district supplied with water by the Nelson corporation) can be dealt with daily. In addition to the source of supply the corporation are possessed of two service reservoirs, with a combined accommodation for 85,000,000 gallons. The sanction of Parliament is also obtained for the construction of two reservoirs, each to hold 40,000,000 gallons, on the Ogden stream above the filter beds, and another to accommodate 180,000,000 at a lower level than the beds. The scheme when completed will place the Nelson corporation in a position to supply a population of 100,000 with water. As compensation for the appropriation of the Ogden stream the corporation will be required to construct, in addition to the existing compensation reservoir in Walverden and the new compensation reservoir, another reservoir near the one just constructed at Black Moss, at the foot of Pendle Hill. The cost of the reservoir opened on Friday is about £10,000.

STATUES, MEMORIALS, &c.

THE DRAKE MODEL AT EXETER.—Devonshire is probably the only county in England where three statues, all facsimiles of each other, exist. The hero of this monument is Sir Francis Drake. His monument, crowned by a bronze figure of the sturdy sea-dog himself, is at Tavistock, and a replica graces the Hoe at Plymouth. Exeter has just acquired Sir Edgar Boehm's original model of the actual work, and has had it erected in the reading-room of the Albert Museum in that city. The sculptor's executors presented this fine study to the South Kensington authorities, and the latter in their turn gave it to the City of Exeter. The statue is of plaster of Paris, painted a bronze colour. It is 12ft. high, and weighs just upon a ton. Unfortunately, in transit from London the figure got broken into no less than 200 pieces, and headless and armless, little more than the actual torso remained intact. In this dilemma, the Museum Committee, put the fragments in the hands of Mr. Harry Hems, of that city, with the ultimate result that the pieces have been so matched and joined together that it is now impossible to see that any accident had ever taken place. The success of this delicate task has been in a large measure due to the courtesy of Mr. Robert Glassby, sculptor, of Holbury-street, Chelsea, son of the late Mr. R. Glassby, managing artist to the Court sculptor, Mr. Harry T. Hems, jun., has carried out the actual work of renovation with the aid of the original small medallion modelled for the colossal statue.

The city council of Rochester have finally approved a new code of building by-laws.

The first portion of the memorial to the late Bishop Lightfoot is rapidly approaching completion, and the cenotaph monument will be unveiled in the choir of Durham Cathedral on the 20th of October by the Earl of Durham, the Lord Lieutenant of the county. The commission to execute the cenotaph was placed with Sir Edgar Boehm, who died whilst his work was in progress; it has, however, been completed by Mr. Alfred Gilbert, A.R.A.

A building situated in Parson-street, Glasgow, and to be known as St. Mungo's Passionist Monastery, is now being completed. Built of red sandstone, the building measures 80ft. by 50ft., and, besides a basement, consists of three floors. It is Gothic in style, and adjoins the Catholic church. On the basement are rooms for a mission library and societies. The first floor contains the library, refectory, a community room, and three public reception rooms. On the second and third floors are 16 bedrooms, and on the third floor is also built an oratory. The Rev. Father Osmond Cooke, of Paris, is the architect. The cost exceeds £14,000.

Our Office Table.

THE Borough-road Polytechnic is to be opened by the Earl of Rosebery to-day. The building comprises the old British and Foreign Training College, with various additions made at different times, full of dark passages, and rooms located on many levels. Some £12,000 has been so far expended, under the direction of Mr. Rowland Plumbé, F.R.I.B.A., in converting the structure into a more convenient shape for the purposes of the present institution; and no doubt the work presented a somewhat difficult problem, on which considerable ingenuity has been expended. The main portion of the new work has yet to be carried out, by building a large assembly hall to seat 1,500 people, and a big swimming-bath on the vacant land to the rear of the existing institute. The usual scheme of an educational character comprises the programme, with gymnasium, social club, and reading rooms, and all kinds of amusement. Clubs are in anticipation, with excursions, and a "House of Commons." Among the items for women is a laundry, to teach washing, with small appliances. This latter, anyway, is a practical idea.

PROFESSOR ROGER SMITH will inaugurate the courses of lectures on architecture to be held at University College, London, through the coming winter with a public lecture to be delivered at the college on Thursday evening, October 6th, at 7.20, taking as his subject "Architecture an Art, a Science, and a Profession." The usual classes on Architectural History and Construction and Modern Practice will commence the following week, and a new feature of considerable importance is the establishment of evening classes for both architectural and constructional drawing at such moderate fees as to bring them within reach of all students.

THE Liverpool Architectural Society has just arranged for a series of classes to be held during the coming winter months to assist in the professional education of architectural students. The classes will be free to students joining the society, and are intended to be a preparation for the R.I.B.A. examinations; they will also assist the student in his office work. The classes will meet every Thursday evening, from 6.30 to 7.30, in the library of the society, Delta-chambers, 15, Cable-street, Liverpool. An examination will be held at the close of the session, and prizes awarded by the council. The subjects to be dealt with in the lectures are: "Sanitation," to be dealt with by Mr. T. Harnett Harrison; "Stresses in Structures and Shoring," Mr. J. Dod; "Building Construction," Mr. David Lyon; "Specifications and Quantities," Mr. H. L. Beckwith; "History of Architecture," Mr. H. W. Keef; and "Mouldings, Features and Ornament," Mr. C. E. Deacon.

At Tuesday's meeting of the London County Council, the chairman read a report of the Building Act Committee, in which attention was called to the conviction of Mr. Henry Parsons, of Shakespeare-road, Loughborough Junction, the district surveyor for South Lambeth and part of Camberwell, for riding on the London and South-Western Railway Company's line for a long period without having paid his fare. He was fined 40s. and five guineas costs on each of two summonses. The committee recommended that Mr. Parsons should be suspended from his office, and this was agreed to.

THE first of a series of lectures and demonstrations for the special instruction of sanitary officers was given at the Free Library, Liverpool, on Saturday afternoon, under the auspices of the Sanitary Institute and the Technical Instruction Committee of the Corporation of Liverpool. The lecturer was Mr. Louis Parkes, M.D., D.P.H., medical officer of health for Chelsea. In his introductory remarks, Dr. Parkes explained the work that was being done by the Sanitary Institute, adding that some people thought that sanitary legislation was going too far, but he was not one of those, especially when he had regard to the circumstances that surrounded people in large towns. He believed in the proper training of sanitary inspectors. Some years ago almost anyone was considered good enough to be a sanitary inspector—a carpenter, a butcher, and so on—and, of course, such men were ignorant of their duties. Now, however, the men selected for such posts must have had a good training and have passed examinations; in fact, some local boards

and authorities stipulated now that the men appointed should be so qualified. In the face of these important facts it was necessary that they should acquire all the knowledge they could in sanitary matters. Dr. Parkes then proceeded with an address on "Ventilation, Heating, and Lighting." To-morrow (Saturday afternoon) Mr. H. Percy Boulnois, city engineer, Liverpool, will lecture on "House Drainage and Sanitary Appliances."

Though shorthand and typewriting have attracted many to this field of labour, so extended has become the area in which shorthand is used, and so generally is the typewriter being adopted, that there is always a demand for well-educated young men and women who write a fair speed in shorthand and can operate the typewriter to good effect. It has been said that a practical knowledge of shorthand and typewriting is more valuable to young people in these days than a smattering of the classics. Very good salaries have been and are being earned by thousands of male and female operators, and though doubtless the inefficient find it harder work to find appointments of any value than was once the case, those who are fitted for this class of work and have gone through a special course of training for it, such as can be obtained at the Yost Typewriter Company, 40, Holborn-viaduct, need have little fear but that their services will be in demand, and will be adequately rewarded. The Yost Institution offers exceptional facilities for rapidly acquiring shorthand and typewriting. Tuition is individual, and the Yost typewriter, which is everywhere so well spoken of, is taught free to students of the Shorthand School, purchasers of machines, and certain clerks in H.M. Civil Service. Shorthand and typewriting combined are working a revolution in business methods, and, quite apart from the question of daily occupation and bread winning, no one who would be abreast of the times should be without some knowledge of these wonderful labour-savers.

MEETINGS FOR THE ENSUING WEEK.

THURSDAY.—University College, London. Inaugural lecture by Professor Roger Smith, F.R.I.B.A., on "Architecture an Art, a Science, and a Profession." 7.30 p.m.

FRIDAY.—Architectural Association. Conversazione at the Imperial Institute, South Kensington. 8 p.m.

The Architectural Association, 9, Conduit Street, W.; and 56, Great Marlborough Street, W.

THE ARCHITECTURAL ASSOCIATION COURSES OF LECTURES, CLASSES, AND STUDIO INSTRUCTION WILL COMMENCE ON MONDAY, October 10.

The Courses are both Elementary and Advanced, and are designed to provide a sound professional education, supplementary to that to be obtained by the prevailing system of pupillage. The Course, which is in four divisions, is progressive and consecutive, and the instruction is given by Lectures and Instructors of known ability.

DIVISION I.

LECTURES AND CLASSES.—The Orders of Greek and Roman Architecture, Building Materials, Perspective, Physics.

THE STUDIO.—Drawing from Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Plane Geometry, Criticism Meetings.

DIVISION II.

LECTURES AND CLASSES.—English Architecture, Materials, Elementary Ornament and Colour Decoration, Strength of Materials, Stresses and Strains.

THE STUDIO.—Designs based upon Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Solid Geometry, Criticism Meetings.

DIVISION III.

LECTURES AND CLASSES.—The History of Architecture, Materials, Colour Decoration, Sanitary Science as applied to Drainage and Water Supply.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Perspective and Sciography, Constructive Masonry, Criticism Meetings.

DIVISION IV.

LECTURES AND CLASSES.—The History of Architecture; Sanitary Science—including Ventilation, Lighting and Heating, Painting, Sculpture; other Arts allied to Architecture; Professional Practice—including Legislative Enactments relating to Building Contracts.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Drawings of Ancient Buildings from actual measurement, Graphic Statics and Perspective, Criticism Meetings.

EXTRA SUBJECTS.

LECTURES AND CLASSES.—Plane and Solid Geometry, Geology, Mensuration, Land Surveying and Levelling, Chemistry of Building Materials, Quantity Surveying—including the Preparation of Estimates, Discussion Section.

THE STUDIO.—Sketching and Measuring, Elementary Water Colour Class, Water Colour Class, Modelling.

A Pamphlet, containing full particulars of the curriculum, may be obtained free on application to the Hon. Secs., at 56, Great Marlborough-street, London, W. Fees must be paid in advance, and passes may be obtained at the Offices of the Association, between Ten a.m. and Seven p.m.

THE OPENING CONVERSATION will be held on FRIDAY, October 7, at Eight o'clock, at the Imperial Institute, South Kensington. The Exhibition of Prize Drawings and the last Session's Work of the Students, and the Award of Prizes, will take place at the ANNUAL GENERAL MEETING of the Association, to be held on October 21, at 9, Conduit-street, W., at 7.30 p.m.

ERNEST S. GALE,
F. T. W. GOLDSMITH, } Hon. Secs.

Trade News.

WAGES MOVEMENTS.

ABERDEEN.—The plasterers' labourers in this city struck work on Friday on account of the masters having declined to grant an increase of wages from 4½d. to 5d. per hour.

LONDON DISTRICT.—It is reported that as a consequence of the reduction in working hours from 55 to 52 hours per week, and the increase of the rate for overtime from 1d. to 3d. per hour, both masons and carpenters are better employed than usual, and prospects are good for the coming winter.

CHIPS.

Further reparations are proceeding on the exterior of the *chevet* of Notre Dame, Paris. All the flying buttresses of that portion of the cathedral, having suffered from the weather, are to be reconstructed; extensive repairs are required to the roofs of the choir and nave; and the traceries of some of the windows are in need of repair.

Further restorations of the parish church, Dewsbury, have been decided upon. Already £20,000 has been spent upon the rebuilding of the chancel and transepts, at first from plans by the late Mr. G. E. Street, R.A., and afterwards under Mr. Arthur E. Street and Mr. A. H. Kirk, of Dewsbury, as joint architects. It is now intended to proceed with a complete restoration of the nave. The interior of the new church was illustrated in our issue of June 17, 1887.

The memorial stones were laid at Burslem on Monday of a Miners' Hall for the use of the North Staffordshire Miners' Federation. The building, which is situate in Moorland-road, adjoining the proposed park, will be a red-brick structure, and will comprise a residence for the miners' agent, offices, committee-rooms, and an assembly room. The assembly-room, which will be used for general meetings of the Federation, is 30ft. by 21ft., and is on the first-floor over the offices and committee-rooms. The large committee-room, which will also be used as a council chamber, is 22ft. by 15ft. The building will cost about £1,500. The plans have been prepared, and the work is being carried out under the supervision of Mr. G. L. Jones, architect, of Waterloo-road, Burslem, and the contract of Mr. W. Cooke, of Burslem, has been accepted.

The directors of the Goole Gas and Water Company, Limited, in order to meet the growing demands of the town, propose to extend their gas and water plant, and to effect this a call of £37,000 is to be made. Boring operations for a new water-supply commenced on Monday near Beaver's Bridge, about six miles from Goole, and it is proposed to build additional gasworks at Rawcliffe Bridge.

Stamford Park has now become the joint property of the Corporations of Ashton-under-Lyne and Stalybridge, and a considerable amount of money is being spent by the two authorities in the construction of ornamental ponds, the extension of forcing houses for plants, and in other improvements. Chadwick's Dam, a large deep lake, which, though outside the park boundary, forms a portion of the same property, is to be so far filled up that the depth shall not exceed 4ft. Mr. J. Eaton is the architect, and Mr. J. Robinson the contractor.

Holloway's Ointment and Pills.—Reliable Remedies.—In wounds, bruises, sprains, glandular swellings, enlarged veins, neuralgic pains, and rheumatism, the application of this soothing Ointment to the affected parts not only gives the greatest ease, but likewise cures the complaint. The Pills much assist in banishing the tendency to rheumatism and similar painful disorders.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with the greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—T. PETTITT and CO., Lithographers, 28, Fitch-street, Soho, London, W. Established 60 years.

AMATEURS AS CLIENTS.

WE are most of us amateurs, in one art or another. When a busy man has, for the time, got through his own business, and wants a little amusement, he generally finds it in taking up, only half-seriously, the business of somebody else. He tries what it is to be a boatman or a sailor, a farmer or a gardener; or, if his fancy is for mechanical work, he buys a lathe or a set of tools. In his own profession he has a poor opinion of dilettante aspirants; but when he gets outside it, and becomes one of them himself, he sometimes thinks more highly of his efforts than he ought to think. This is the case even in those arts which, as everybody admits, require a previous training. How natural, then, that it should be so in our own—of which few outsiders ever learn enough to discover that it even needs learning. The builder who has put up, "out of his own head," a row of houses in an East End suburb, fancies himself an architect; and the gentleman of leisure, with some taste and some faculty for sketching, is possessed with the same idea, on rather better grounds.

The world thinks highly of the amateur architect. If he has suggested a plan, popular belief gives him the credit of the whole performance, including design, construction, details, and superintendence. Go, for instance, to the Oxford University Museum. It was thought a marvel once, in the palmy days of Ruskinism, when the eloquence of the "Seven Lamps" and the "Stones of Venice" made the public fancy for a brief space that flabby naturalistic carving was a noble thing. The details, which were its glory once, are rather its disgrace now the world is wiser; and yet there are marks of genius in the work which show that its author was no ordinary man. Though led astray for the time by the delusions of his day, he was too inventive and original to have been detained by them long; and had he lived, he would probably have become a leader amongst us. No other architect could have produced the Oxford Museum; and yet its architect's name is hardly mentioned there. The attendants tell you, if you inquire, that the real architect was a late eminent professor of geology, the truth probably being that this professor just sketched out the arrangement of the courts and chambers. Having done this, the public set him down as the author of the whole structure, from foundation to finish. One can hardly help suspecting that what happens now often happened in the Middle Ages. When we read that this bishop or that abbot was the architect of his church or cathedral, the scepticism which comes from experience sees him painfully drawing on parchment a plan of his nave and choir, his aisles and transepts. That done, and the dimensions settled, it discerns him cheerfully turning over the rest of the design—that is, about 95 per cent. of the whole—to some master-mason and his craftsmen. It was they who invested the scheme with artistic merit. It was they who made it possible as a piece of construction; and it may be they would often have made it better than they did if they had not been hampered by the great man's ground-plan at the outset.

It does not take much to make a man suppose himself an architect. Look at the case of the Faddleton Sunday-school. The site was secured, and plans were about to be obtained. Suddenly it dawned on a good man—a member of the building committee

—that he himself was by descent an architect, and was capable of producing them. His father, whom he lost in his infancy, had been a land surveyor, and, amongst other things, had left him a measuring chain and a two-foot rule. He hunted them up. The chain, though imposing in aspect, did not seem to have any vital relation to the business in hand; but the two-foot rule was invaluable. By its aid he drew out a ground plan of the building; it was just such a plan as anybody would be likely to draw who had never drawn one before—namely, a plain oblong, without classrooms, without porches, without offices. Wide enough to touch the adjacent buildings, it would have required on each side of it a lead gutter about 70ft. long, supplying a prospect of useful work for teachers and children in shovelling away the snow after every storm. He was delighted with his feat, and his fellow-committeemen were equally delighted. They thought, as many people who would be indignant at being called ill-educated still think, that all the drawings a building requires are a ground plan and a view of the outside; consequently they considered that he had made exactly half of them, and that the architect they might select could not in conscience expect more than half his commission. Hope, in this case, told them a flattering tale. Several things were clear to all the professional men they interviewed. First it was clear that there would be more trouble in making the sections and elevations fit the amateur's plan than in working out a new scheme altogether. Secondly, it was obvious that if this plan was built from, all its faults would be laid on the architect. And thirdly, it was so extremely defective that no architect would take any responsibility with regard to it. The committee, with sighs, and almost with tears, had to give it up; but they would tell you to this day that they did so in consequence of professional jealousy. They do not realise that a man is not necessarily an architect because his father was a land surveyor.

The gentleman amateur stands on a higher level. He has some acquaintance with architecture, at least from the outer side. He has travelled about and cultivated his taste, and does really, to some extent, know good from bad. His criticisms are often sound; it is only his suggestions that are troublesome. He has seen something abroad which he remembers with pleasure; he wants to do something like it at home, for a different purpose, in a different climate, with different materials. He is disappointed if his architect explains that for these reasons the thing may prove a failure; he is still more disappointed if he is not cautioned, and it turns out ill. Or, again, he imagines a design for himself which he would like to have built, and he tries to explain it and get it put on paper. To work out one's own half-grasped conceptions is no easy matter, and to seize upon those of another person, and embody them in brick and stone, is more than can be expected from human intelligence. Here and there, perhaps, an idea is taken hold of and used; but in all probability it jars with the work by which the designer has to supplement it, and if this does not happen, and if he takes up the conception with all the goodwill in the world, he cannot carry it out with the life and spirit which he would have put into some thought of his own. It turns out tame and flat, if not full of incongruities, and, naturally enough, there is disappointment again.

When the amateur is going to build a house, he is fond of sketching out its plan. And herein he is doing a useful thing, if he will let this plan merely serve as a statement of his requirements. It will give his architect, in that case, a great deal of valuable information. It will show what sort of a hall, what sort of a dining-room and drawing-

room and library the client wishes for, and in what sort of position he would prefer to put these and the other apartments. Here and there it may contain suggestive points, worth noting and incorporating into the future structure. The common mistake is that of handing it to the architect as a scheme to be exactly followed. The arrangement may, or may not, be convenient; but there is a great deal to be thought about in making a ground-plan, besides its convenience. It may be convenient, and yet very costly; it may be convenient, and yet difficult to roof without lead flats and lead gutters; it may be convenient, and yet badly lighted or structurally weak, or objectionable in fifty other ways. If these things are so, the plan ought to be modified; but to get it modified may require some tact. The most beautiful thing a man sees is, according to an Eastern proverb, the work of his own hands; and of all his works, the best-beloved is usually the earliest and most imperfect. The pupil's first design!—how admirable it seems to him!—what visions of loveliness he beholds in every line and curve! The more designs he makes, the less satisfied he feels with them; and at last, when praise is coming in from all quarters, nothing would please him so much as to see his best building burnt down, and to know that he would be allowed to put it up again with improvements. The amateur is in the position of the pupil. Unless he has worked out a great many plans before, he will be tempted to think his plan absolutely right; and it will not do to let him find out his mistake by carrying it into execution. "If you knew it would not answer, why did you not tell me at the beginning?" will then be his question. The architect will get all the blame if it fails, though the owner, perhaps, would have appropriated all the merit had it succeeded.

There are amateurs of many sorts, but we will only refer now to those of the fussy sort. They are often fair and just in intention, but troublesome beyond human endurance. A good man of this class, who will now trouble no architect any more, used to live about twenty miles from London. He had much landed property, and lived in a larger house than he required. In this he made constant alterations, bit by bit. His architect lived in daily fear of hearing from him. At one moment he would write, "Pray come down by the 1.30 train to-morrow, as I am thinking of altering the library window from eight panes to either four or six, and I wish to have your immediate advice about it." Next week he would send a note to say that he wanted to consult on the spot as to the best place for the scraper; and soon afterwards, the new panel which had been put into the back-door would require instant examination, as it exhibited most alarming signs of shrinking. All this would be very well, if an architect received for his journeys the same fees as a fashionable doctor. Under the actual conditions, it is not at all well. Details, of course, must be looked after; but when they have to be looked after, one by one, in this way, some other mode of payment than that by commission becomes an urgent necessity. In this case, the architect did his best—not merely for his own credit, but for the sake of obliging a client who was in many ways deserving of respect. He did not, however, reap the reward he might have looked for. The client ended by pulling down his large house, and building a smaller on the same site; but he called in a fresh architect for the purpose. The moral is, that there is no satisfying the fussy type of amateur, and that the best course to adopt is to keep clear of him altogether.

ART IN IRON ROOFS.

SINCE Hodgkinson and Fairbairn first essayed in iron, the design and development of the iron roof have made considerable

strides in this country, notwithstanding the strong prejudices which iron has had to encounter from the profession. These prejudices were mainly based on objections to the employment of a new and untried material, and the abandonment of timber, so long associated with the noblest examples of constructive skill. With the experimental knowledge derived from important engineering works, the former of these objections has been gradually removed, perhaps not entirely, but sufficiently to give architects confidence for the future. The latter objection—the dislike to give up timber—however, is still potent, for we find that even for wide roofs timber is preferred whenever the building aims to be something of a more ornamental kind than a drill-hall or a railway-station. The fact is, simply, that there is more adaptation in a roof of wood. It can be designed with reference to architectural effect better than one of iron; it is more substantial in appearance as a visible roof, and for decorative purposes it is decidedly superior. In a word, the architect can get more out of it. An iron roof must be a truss of some sort, and the principle of its design must be that of resisting tension mainly with the smallest members compatible. We cannot give to them the substance of wood, on account of increased weight. For instance, a principal or a wrought-iron tie-rod of large section would be heavy and uneconomical in the extreme, without any compensating advantage whatever. How iron might have been treated if our roofs could be cast in sections and bolted together like the cast-iron ribs of an arched bridge one can only conjecture. For example, we might have an iron truss of two halves, each of cast iron and bolted together, that would be sufficiently strong against all risks, and substantial in appearance, were it not for the weight of iron. Take two unequal-sided triangular frames of cast iron, and putting together the shortest sides, bolt them together to form a roof-truss. The open spaces could be filled with ornamental ironwork, either cast or wrought. We might imagine the old hammer-beam and ribbed types of roof, like those over Westminster Hall, Hampton Court, Crosby, and Eltham halls, cast in sections and erected. They would at least be stronger and more durable than timber, but their weight would be objectionable. For structures of small span, cast iron might be used, but successful precedents are scarce.

Lately there has been a growing desire to adopt iron roofs over large halls and lecture-rooms in buildings of an architectural character. Many of the designs now made for municipal buildings in which large central halls are provided have iron roofs to support the outer covering, with plaster or other ceilings underneath. For this purpose the value of iron construction cannot be questioned; the roof can be made lighter and of flatter pitch if need be, to say nothing of its greater durability. In many of our public libraries the reading-room and reference-library are covered by iron roofs, and in large congregational buildings it has been used, but we cannot say with much artistic success. In many of these buildings, however, the iron roof forms the outer covering, and does not show internally. No attempt is made to represent it otherwise than as a plain wrought-iron piece of construction, so that in this manner the engineer, rather than the architect, is consulted in its design.

The history of iron roofs of wide span would form an interesting digression from our present remarks, and it would show how much, or perhaps we ought to say how little, has been accomplished to make the wrought-iron roof architectural. One of the first wide-span roofs erected was that at the Lime-street Station, Liverpool, of the London and North-Western Railway. It was put up

in 1849, forty-three years ago. The span is 153ft. 6in. This roof is of the arched or bow-string class, with radiating struts from the tie-rod; the trusses rest on cast-iron columns 21ft. apart, and to the underside of girder the height is 56ft. The bow-string truss has developed into many forms to be met with over some of our great railway stations, as those of Birmingham (New-street Station), the Victoria, London Bridge, and Charing Cross. The tie-rod truss is well suited for the large spans of railway stations and industrial halls, and the iron roofs over some of the new buildings for the forthcoming Columbian Exhibition at Chicago show the progress that has been made in iron construction of this class. Thus, the Industrial and Liberal Arts building has an iron roof of 368ft. span, it being erected over 200ft. high, and on columns 50ft. between centres. For spaces of large area probably no other class of truss is more suited, and the angle braces, which come down below the springing level of the principals and connect the line of columns, cutting off the angle between the latter and the tie-rod, are great improvements to the appearance of the roof, and add materially to its strength and resistance to wind lifting. Another class of truss is that formed of arched ribs without ties, which are prevented spreading by the ribs being brought down low, or nearly to the ground, as in that of St. Pancras Station, which has the tie underground, and that of the Olympia, where the horizontal thrust is provided for by one part of the arched rib being continued vertically down the columns and the other part branching off to form the gallery roof. Considerable architectural effect may be obtained by arched ribs of this kind, either open and latticed or solid. The arched ribs of the Agricultural Hall, Islington, exhibit a roof of this construction. Of the open braced kind, we must name the steel arched roof of the Electricity Building at the Columbian Exhibition, the inner member of the arch springing from the floor. The truss or tie-rod class of structure is obviously less suited to an architectural design; it has an unrestful look about it, and all its stability depends on the fragile tie-rod and the connecting-rods and struts. If we can imagine a truss of the bowstring type filled up with a solid pierced web of crescent shape, a more stable form of roof would be the result, at least to the eye, but the construction would be less economical, as lightness would be sacrificed. One of the greatest roofs of the arched rib class ever constructed was probably that of the roof over the machinery hall at the Paris Exhibition of 1889, the clear span of which was 377ft., the ribs being made of steel, hinged at their bearings on the ground level and at the crown. These pivots enabled the roof to accommodate itself by expansion and contraction to changes of temperature. The chief weakness of all truss forms artistically considered is that they spring abruptly from their walls or supports, whereas the arched rib may be brought down below the rafter springing level, the spaces between the curved ribs and the rafters, or the spandrels and crown, being open for some kind of pierced work or ornamental filling.

Having shown briefly the two principal kinds of iron roof, we may now inquire why it is they have failed to become architectural features. One of the main causes is no doubt to be found in the fact that this class of structure is still exclusively in the hands of manufacturers, who are required to produce something economical. Whenever an iron roof has been erected, the question of economy has been uppermost. It is generally a cheap mode of roofing a large space that is thought of, such as a railway station, a huge exhibition building, or hall. We have another reason why the iron

roof has not become a favoured object of the architect's attention, namely, that it is generally concealed by a lower ceiling in architectural buildings. Except in large structures, the iron roof has generally been the outer covering, and therefore not visible below. For this purpose the ordinary forms of truss have been used, and little opportunity has been given to design an iron truss, or to consider it in the same category as the wooden one. Until the iron truss is made a visible part of the interior of a building, architects will be content to allow the design of it to be left to the engineer. A few instances of iron roofs over large public halls and Nonconformist buildings may be cited; but owing to the causes we have pointed out, they have not come up to the artistic standard of the old wooden roof. The ribs look weak, and spring badly from the walls or the spandrel, and the ornament introduced of cast iron is of an inferior order. The great point to be aimed at is to bring down the truss below the springing or wall-plate level, to consider the ironwork as part of the structure. If architects would regard the iron roof as they do the timber one, and endeavour to divest their minds of the ordinary engineer's types of tie-rods and tension members, introducing cast iron in parts subjected to simple compression, we may one day see a more artistic discernment of iron as a material for the purpose. For churches, the timber construction will continue to hold its place till a more substantial class of iron roof is to be found than that which has been adapted over structures of a more or less temporary character, or which have so little permanence expressed in their design.

APPLIED ARCHITECTURE.

WHEN so many specialised forms of construction engage the attention of the architect, it is necessary that the educational facilities afforded to students should be abreast of the time. The antique models, examples of ancient and modern architecture, diagrams and apparatus, found in our public institutions and colleges in which architecture is taught are no doubt valuable means of instruction in the hands of competent professors who are engaged in teaching the elementary principles of art, but they fall very short of those requirements which now often tax the mind of the practising architect in those special "lines" of construction which may be regarded as special branches. It is for this reason we have pleasure in drawing attention to the announcement that the authorities of King's College, under the direction of Professor Banister Fletcher, have established a museum replete with models, drawings, casts, specimens of various kinds, admirably adapted to the requirements of architectural students. This collection has been in formation during the last two years, and includes examples from Italy, France, and the Continent generally. Visits by Prof. Banister Fletcher have been made for this purpose. The photographic illustrations in the corridor include interior views of the Pantheon, Rome; St. Clement, Rome; Basilica of St. Apollinare in Classe; Mausoleum di Galla Placidia, with its simple vault; San Miniato, Florence; Pisa and Siena Cathedrals. Fine examples of Renaissance are given in the unique doorway of the Palazzo Vecchio, Florence, and a stone mantel-piece of the Bargello Museum in the same city; but it would be unnecessary to particularise. Every important ancient and modern style is represented, Egyptian, Greek, Roman, Romanesque, Byzantine, Italian, French, German, and Belgian Gothics. The English styles are equally well represented in a good selection of typical illustrations and plaster casts. These illustrations are mainly from the col-

lection of Professor Banister Fletcher. The museum contains specimens of all the chief woods and stones; of the latter we notice several blocks of the several varieties of stones quarried by the Bath Stone Firms, samples of terracotta and pressed-facing bricks supplied by Mr. J. C. Edwards, of Ruabon, models of parquetry floors, &c. The models of roofs, trusses, framed floors, and partitions are well selected. The facilities at King's College include an architectural studio for assistants and others, and classes for constructional drawing and quantities, in addition to the day and evening classes.

The many admirable textbooks and technical manuals now published on every branch of the building trade ought to make our rising architects very competent in all the technical parts of their profession, if, indeed, such means of instruction can do so. In future we may expect our young architect to be skilful in technical crafts; we may expect him to be able to use the tools of the carpenter and joiner, to "true-up," square, gauge, set out, and chisel any piece of wood; to be able to make a rectangular or octagonal prism or cylinder of wood, to dovetail, mortise, and make boxes and drawers, and to frame an ordinary door. At least we may expect him to know how to set about these operations, without going so far as to say that the manual training is absolutely necessary for the architect to go through. No doubt he is all the better equipped for the duties of his profession in making working drawings if he is so qualified, though we cannot fully endorse the proposition that a manual knowledge of the trades is absolutely necessary for an architect. As an exercise for the training of the eye, these operations are of value. For instance, the practice of "trueing-up" a piece of wood with a jack-plane, taking off the rough parts and testing by means of a try-square and winding sticks; shaping up models of moulded bars like the spoke of a wheel, must have a beneficial effect and become an education to the eye. Models and diagrams of these objects ought to be in every technical museum, as well as those of the advanced stages of framed work, as roof trusses, staircases, and handrailing.

But there are other and higher object lessons to be kept in view. Technical instruction should be applicative to every kind of building. The operations of carpentry and joinery, applicable to matters like roofs, partitions, doors, and staircases are elementary. We want instruction in planning theatres, technical school, libraries and classrooms, hospitals, baths, public libraries, and many equally specific kinds of buildings, about which there is very little published information extant. Such details as have been given by Mr. Ernest A. E. Woodrow, A.R.I.B.A., on theatres in our pages are of value. What, for instance, should be the rule for arranging and adjusting the seats to the isacoustic curve, so that every spectator may see the stage; the mode of planning the pit and stalls, the dress circle, second circle, and gallery so as to obtain desirable sight lines, are points that ought to be learned by every architect; but, as a matter of fact, the question is one left to experts in theatre construction. So also every student should be taught how a classroom and a laboratory should be arranged so as to afford the proper light, and how the benches and fittings ought to be designed. There should be some accepted principles of these points, which ought to be known as a part of the grammar of planning. Of the other special buildings we have named, the knowledge to be learned is equally certain and specific, and good models of the requirements and fittings should be found in every architectural school or museum. Hitherto we have had no specialisation of architecture; all has been too general (applicable to every building alike) to be of much value to an architect who is called upon to design any

of the structures we have named. The old régime, while it made skilled constructors and builders, taught nothing of any particular arrangement. A certain consequence has followed—viz., that specialists have had it all their own way in theatre building, hospital and technical-school construction, &c., and even in church building the architect who has made himself a master of ritual requirements is generally employed to design the largest churches. These gentlemen have monopolised certain branches in consequence. But there are two stronger objections to be urged against specialist architects: first, they have not that knowledge of art which is necessary to produce the highest results artistically. Thus, a designer of factory buildings, workshops, breweries, and the like may inflict much pain on the sensitive artist, as he frequently does as a matter of fact. Again, while a class of buildings is in the hands of a few experts, perhaps only two or three, improvements in design are less likely to be sought for, as the specialist has a great aversion to make a new track or to break through old traditions. On the other hand, when the whole profession are generally learned in the requirements, many artistic minds are directed to the problem, and there is greater chance of competition and improvement. A clique of architects who are making a fortune in one branch are not likely to impart to others the elementary principles and data. We have a superabundance of books, models, and illustrations of the Classical and Gothic periods, but scarcely any explaining the many recent applications of architecture to commercial, educational, hygienic, and technical pursuits and requirements. Construction in iron, timber, brick, and other materials has been fully exemplified, but if we want to know anything of fittings for certain purposes, we can only obtain the information by examining buildings in which they are provided, or by consulting specialists or manufacturers.

IRON ARCHES OF LARGE SPAN.—II.

CAST IRON.

THE value of the "inertia" of any particular cross-section, which very materially depends upon its relative proportions, having once become recognised, led, before long, to the adoption of a different form for every description of cast and also wrought-iron beams. The modern cross-section, both in England and the Continent, for cast-iron arched ribs, is that of the double equal-flanged system, of which we shall adduce, subsequently, some practical examples. In order, however, to point out that an intermediate form between the plank-on-edge section, described in our first article on this subject, and the present type in use was formerly introduced, we give an illustration of it in Fig. 2.

Fig. 3.

Fig. 2.

There is also another reason for drawing attention to this form of cross-section, which is well worthy of consideration, as it involves a question which has been discussed by many eminent authorities, who are by no means *d'accord* respecting its solution.

The section shown in Fig. 2 is that of the arched rib of the "Standish Bridge," which, though it varies in depth, yet retains the general form given in our illustration. The depth at the crown of the arch is 1ft. 6in., and except that the breadth of the lower flange is in point of magnitude largely out of proportion, the shape strongly resembles an ordinary contractor's or Vignoles' single-flanged rail. The dimensions of the lower flange are 9in. by 1½in., while the breadth of the head or top (for it cannot properly

be termed a flange) is 3in., and the depth or thickness 2in. The thickness of the middle part or rib is 1½in., which is not more than what is about sufficient for it to do its duty in maintaining the top and bottom parts at their respective distances, and so preserving the stiffness of the whole cross-section. In estimating the strength or the moment of resistance of this form, it would be advisable to neglect the area of the middle part, and so err, if at all, on the safe side.

An inspection of Fig. 2 indicates that while the shape of the cross-section is not that usually adopted for cast-iron arched ribs, neither is it the proper form for a cast-iron beam or girder. The correct relative proportions for the respective areas of the top and bottom flanges of a cast-iron girder are as one to six, and not as one to two and a quarter, which latter ratios are those of the head and lower flange of the section in Fig. 2. It would appear, therefore, as if this section were designed to act, partly, although imperfectly, both as an arched rib exposed to solely a compressive strain, and also as a girder, subjected to a strain of a transverse character. Although an arched rib, whether of cast or wrought iron, is usually regarded as being acted upon by a compressive strain alone, yet—and this is the question we drew attention to—under certain conditions of loading it is stated that it has to behave similarly to a horizontal girder of the same span. In what exact proportions it has to discharge this double duty has not been satisfactorily determined, although there is very little doubt that the girder principle, if it does exist in this type of construction, plays a very subordinate part in comparison with that of the arch.

Another practical example of flanges of unequal area is shown in Fig. 3, which represents a cross-section of the cast-iron arched rib of the bridge over the Thames at Barnes. The flanges are 30sq.in. and 16sq.in. respectively, or in the proportion nearly of two to one. They are not of the same thickness either, the lower being 3in. and the upper 2in. thick, which latter dimension is also the thickness of the middle part or web. Independently of the part played by the breadth of the flanges with respect to the "inertia," or moment of resistance of the cross-section, as already pointed out, the stiffness of the rib is greatly augmented, by a proper proportion being maintained between the values of b and d . It is evident that in unequally double-flanged sections, similar to that in Figs. 2 and 3, the neutral axis and the centre of gravity do not pass through the centre of the cross-section—that is, that the equation $x = \frac{d}{2}$ no longer holds. It is obvious

that the position of the centre of gravity will be shifted nearer the flange, which has the greatest moment of resistance, which is, *ceteris paribus*, proportional to the sectional area. In order to obtain the position of the centre of gravity for a

Fig. 4.

similarly shaped figure, let Fig. 4 represent an unequally doubled flanged section, and assuming the thickness of the flanges to be small in comparison with the depth, as it usually is in practice, and also that the vertical rib is neglected, let AB be the position of the line sought for. Put d for the depth between the centres of the upper and lower flanges, and let x and x_1 be the respective distances from those centres on each side of the line AB . Make $a =$ area of upper flange, and a_1 that of the lower flange, and $A =$ the total area $= a + a_1$. Multiplying these values by their leverage, we obtain for their moments $a \times x_1 = a_1 \times x$. Substituting for x_1 its equivalent $(d - x)$, we have $x = \frac{a \times d}{A}$. If d_1 be the depth of the vertical rib, its centre of gravity will be obviously in the line $CD = \frac{d_1}{2}$; and by similar reasoning, a new position for AB may be

found for the entire section. The practical corollary to be deduced from these investigations is, that however we may shift the position of the neutral axis or centre of gravity, the sum total of the results will depend upon the value of d , the great factor in the strength of all beams and girders, no matter what may be the form of their particular cross-section.

The largest cast-iron arch ever contemplated was one over the Thames, with a span of 600ft.; and it is very possible that had the "overhang" principle for erecting bridges been as well recognised and practised then as it is now, the project might have been carried out. As it is, arches of steel, with a span of 550ft., have been built in more than one instance with perfect success. It is a matter of professional history that, owing to the impossibility of erecting centring at the Menai Straits, it was proposed to construct a bridge of two cast-iron arches, each 350ft. in span, with a rise of 50ft. The design for the intended structure was an exceedingly handsome one, and would have been a great improvement upon the present tubular type of bridge. The arches in question would not have consisted of separate segments of cast-iron ribs, but of voussoirs of that metal, built up successively one by one on opposite sides of a common pier, and held together by strong horizontal tie-bolts. Had the arches been composed of segments of an ordinary rib, there is no reason why the same process would not have been equally available for maintaining the equilibrium of the two semi-arches until the centre length was keyed in. It was, no doubt, the stone arch, with its numerous voussoirs or ring-pens, that suggested the same mode of construction with the more modern material. Cast-iron voussoirs was used in the construction of Sunderland Bridge over the river Wear, and were simply of the ordinary shape, measuring 5ft. in depth and 2ft. on the line of the extrados. While this bridge was in course of erection, six of these voussoirs or blocks were held in place by iron tie-bars. The span of this example of arch construction is 236ft., which is within 4ft. of that of Southwark-bridge. In the proposed structure across the Menai Straits the voussoirs were intended to be hollow, and measure 9ft. in depth by 4ft. on the extradosal line. Although, for reasons that are well known, this cantilever or bracket-arch design was abandoned, yet the opinion prevailed that the principle was susceptible of application upon a much more extended scale than was necessary for the large spans of the Britannia Bridge.

ARCHITECTURE: AN ART, A SCIENCE, AND A PROFESSION.*

FOR clearness' sake, I will at starting define exactly the objects I have in view in this address. First, then, we will consider what is an art; we will examine the nature of an architect's work, and I will endeavour to show that architecture is justly an art. We will then consider what is a science, and will see in what respects architecture is a science. We will thirdly consider a profession, and I will show you that the serious exercise of the art and science of architecture constitutes a profession. You will, perhaps, by this time see that the drift of the title lies in the one short word, *and*. I substitute for an *or*, which insinuates doubts that I call mistaken, the other conjunction which is meant to imply that there is no doubt at all. There will only be time at the close to allude in the briefest manner to your preparation for the exercise of this profession by the pursuit of such studies as form the occasion of our meeting here this evening, and in other ways.

An art has been defined as "the power of doing something not taught by nature and instinct." Obviously, no natural gift, no skill gained unconsciously and in a natural way, is an art. The word *arts* in the plural has an extremely extended significance, and may be used to cover all the kinds of learning and knowledge that are called liberal pursuits. The word *art*, on the other hand, has often a narrow meaning, and is limited to the sort of skill which is directed towards objects of beauty. More correctly, this sort of art is called fine art, but we usually now refer to painting, sculpture, music, architecture, and the related pursuits as

pre-eminently the arts. This, however, is not strictly accurate. When we talk of an art it may or may not imply the possession and use of learning and knowledge, and it may or may not imply the exercise of trained and cultivated taste and the pursuit of beauty; but it always means a skill that does not come by nature. Though there be a distinction between an art as thus described, and a fine art demanding cultivated taste as well as skill, the relation between the two is still very intimate; the links, for example, which connect the art of the sculptor with that of the jeweller, or even the potter, are close ones. There must be the same highly-trained manual skill, and the same intimate knowledge of the materials used. The same clear and definite perception of the aim to be attained is needed for success in either. There is, of course, between most of the industrial arts, taken as a whole, and the fine arts, a difference which is conspicuous enough, but it is not always recognised that the whole of the arts are connected together to a remarkable degree by the fact that trained skill is in each case indispensable to those who would pursue them, and that there is not often a hard-and-fast boundary-line distinguishing the one from the other. He that pursues an industrial art is called an artisan; he that pursues a fine art is called an artist; but many an artisan is an artist as well. Is architecture an art? And, if so, is it a merely industrial art? Is it one of those nobler arts, like surgery, which stand out prominently as dignified, and yet may have nothing to do with taste and beauty, or is it a fine art, like the pursuits of the musician or the painter? Architecture obviously does not resemble arts such as are generally called industrial. Architecture is not an industry. It, however, has much in common with what I have described as the nobler arts; it has also much in it of the fine arts. Let us for a moment consider how much, and let us, with this object, examine the nature of an architect's work. The architect has to exercise trained skill at every step, and he depends upon that skill for his success. It is not a natural gift which enables him to grasp the requirements in the case of any intended building: this, which must be done as the first step, is only possible after very considerable experience and training; yet, if it be not clear to the architect what the requirements are which he has to provide for, his work is compromised at the start. Again, the power of grasping the nature of the site which a building is to occupy—selecting the exact position, and blending or contrasting the intended building with its surroundings, is an acquired skill; in short, an art in itself. Again, the skill which can rapidly and surely contrive and plan a scheme that will meet the requirements when the latter are clearly understood, and will fit the site, is an acquired aptitude, and one that needs cultivation and constant practice to develop it, and without which the architect is unable to produce a building fit for its purpose. When the architect proceeds to design his building, he begins by planning it—that is to say, designing and arranging the shape and size of the floor or floors on which the affairs which the building is for can be most conveniently transacted, together with the walls to inclose them, the openings for light and access, and, in any complicated plan, the communications. While this is being done, however, other considerations must be present to the mind. The shape or shapes given to the building must be such as can receive a suitable roof, and such that out of them shall naturally grow an exterior and interiors with good architectural character. It is impossible to exaggerate the importance of the plan as a factor in the design, and only by trained skill can the architect embrace these various and often conflicting needs at the same time, and combine and contrast, change and recast one part after another till he has achieved that triumph of technical skill—a good plan. We have said that the appearance of the building has to be borne in mind from the first, and as the planning proceeds, the designing of the exterior and interior must be taken up and proceeded with; and here a skill and a taste bred only of cultivated training, practice, study, effort, and some spark of genius, or, at least, some treasure of talent, is called for. With main forms shapely, well-proportioned, harmonious where a quiet effect is right, or contrasted where brilliancy is needed; with features each in its place, and

each itself good; and with mouldings, enrichments, ornaments, and colour, each studied and each characteristic—the architect must gradually build upon paper a series of elevations and sections which his skill enables him to make, such that if carried out the building shall have beauty, and such dignity, or grace, or other quality as best fits its nature and its site. Another claim on that skilled capacity which makes up the art of the architect, and one, perhaps, as difficult to comply with as any, is made by the financial question. Rarely has the architect *carte blanche*; rather, as a rule, he is closely limited by a fixed amount to be expended, which may not be adequate to enable his ideas to be carried out. In most cases it is essential to success that strict economy be observed, by which I do not mean mere cheapness, but a vigilant eye to keep out everything in the least superfluous, and a careful adjustment of the entire project to the funds at the architect's disposal. In this respect our work is placed under conditions with which the painter has nothing to do, but which are not dissimilar to those governing the sculptor's work. They press often very heavily on the architect, and yet ability to conform to them is one of the parts of our art most imperatively necessary. To put the case in the fewest words, the architect is spending someone else's money. He is bound to spend it like a careful trustee. He is expected to be able at a very early stage to foresee what the cost of carrying out his design when it has been matured will be, and the success of the undertaking not a little rests upon his success in doing so. Another peculiarity inseparable from the position of the architect, and one of the difficulties besetting the exercise of his art, is that he has to build through others. He cannot execute with his own hands the works which he designs and produces. An army of carpenters and joiners, masons, and bricklayers are at work erecting the building, each not unlikely to fall into mistakes and mar as well as make. The architect must supply such plans, such specifications, and such supervision that it shall be easier to go right than to go wrong, and that the many hands engaged may work to one end. I quite admit that from one point of view the modern system of management by which in most parts of England one contractor directs many trades, diminishes the difficulty which I have described compared with what it was at the beginning of the century; but if it makes it easier to direct a miscellaneous body of operatives, this practice introduces a new and a not less serious possibility of difficulty of a different sort. In short, the dealing with men, with contractors, foremen, artisans, clerks of works, and last, but not least, with employers, committees, and official persons, is a part of his art in which the architect requires to be skilled. Fortunately a good routine exists, and scrupulous attention to it will enable a reasonably sagacious man to avoid many of the difficulties; but even to gain a familiarity with that routine is part of the requisite training. One of the most interesting, as well as the most important, branches of an architect's work, is his supervision of his building during its erection. The methods pursued at the present day require a great deal of foresight to be exerted. We build our buildings on paper complete, long before we build them in bricks and mortar; but when the paper work is done, the exercise of the architect's skill is only begun. The superintendence of a work consists in part in watching the materials, and the putting of them together to see that the one is sound and the other workmanlike; but it means also watching the architectural quality of the work, as it gradually emerges from the ground and takes shape, in order to see that that shape is what it ought to be, and, within limits, to better it. A skilled and vigilant architect can do much to perfect the quality of his executed work by minute attention to details as they go on. Beyond this comes the question of improvements. Few minds cease working at any stage short of the end of an undertaking; and the architect or his employer can often see how to modify for the better a building which is in progress. This is sometimes a misfortune, as well as an advantage, and part of the architect's art is to know when not to change, and when he had better change his work as it goes on. Nothing connected with building is more full of risk; and a most unfortunate quality of mind is that fluctuating taste which before a work is well begun desires to change it in important particulars. Over-supervision is also a defect, and one

* By Professor T. ROGER SMITH, F.R.I.B.A. Portions of the opening Lecture of the Session 1892-3 at University College, London, delivered last (Thursday) evening.

part, not an inconsiderable part, of the art of superintending a building is to be able to let well alone. It may be objected that in this description I have mixed up things which everyone would admit to be art with others to which some would desire to give another name. But I reply that every part of what has been just described is essential. If a building is designed and carried out without any regard to the architectural qualities which it ought to have, if it is vulgar, unpleasant, ugly, we all recognise that an essential point is missed; but if it is badly planned, or carried out defectively or profusely, the architect has equally missed an essential of success in his art. The quality which we are about to consider under the name of science must lie at the root of the art, or the result must be incomplete,—not to say imperfect.

In considering architecture as a science, let us remember that the primary and simple meaning of a science is the sum of that which is known and knowable about any given subject. There are various directions in which the architect has to accumulate knowledge, and various sources which contribute to the science of architecture. The first of these is construction. The architect must know out of what materials his building is to be made, and how to deal with them; what is necessary for stability, what for solidity, what for durability; what are the defects or the bad qualities of each material, and what is its special excellence; and how the defects are to be remedied and the good qualities utilised. He requires to know how building is done, and that in various localities and with various arrangements; and he should be abreast of all the improvements of recent years, the new materials, new modes of manufacture, and new possibilities; but while he is to be aware of what is newest, he must also be master of what long experience has established. In short, *building* is the architect's business, and, unless a knowledge of building which is at once accurate and extensive forms part of his equipment, he will do badly. This is the more important because all the noble qualities which architecture can impart to mere building grow out of sound construction. Such fine features as the arch, the dome, the vault are only pleasing because they are structurally part of the proper constituents of a building, and proclaim themselves such. When the eye, indeed, once perceives that a feature, even if richly decorated, is not structural, it loses more than half its charm. At the present day the introduction of steel and iron into buildings is the great novelty in construction, and no architect can afford to be unfamiliar with the qualities of these materials, or to be unprepared for the necessity of employing them should it arise. The extensive possibilities opened out by the use of terracotta, the various ways in which Portland cement has rendered strong and stable building more easy than before, and the many varieties of tiles obtainable, may be taken as less capital examples of modern methods which must be mastered. I spoke of various directions in which the science of architecture has been developed. Construction is one, sanitation is another. Not only should the architect be able to design and calculate his own beams and stanchions, he must also be able to arrange the drains, the water-supply, the heating, lighting, and ventilating of his buildings, and that in a manner such as to be fairly abreast of modern practice in this respect. A further branch of the knowledge for which I am pleading, and one constantly ignored, deserves mention. I refer to the transmission of sound. How often do we find a fine church in which no one can preach so as to be heard; a court of justice in which the keenest ear can hardly catch half the proceedings; a public hall where no speaker can escape an echo? Now, it is not caprice and chance which occasions these failures, though it soothes our self-esteem for us to say so when we have failed. The truth is that a certain amount of attention to what is known about sound, and of keen observation of buildings already erected, would have rendered the architects and their employers an inestimable service as showing what was likely to lead to failure, and how to avoid it. The last branches of the science of architecture to which it is necessary to direct your attention is of a different nature to the ones just alluded to. A competent knowledge of some at least of the forms used in architectural design, including under the word forms general masses, features, mouldings, and enrichments, is quite indispensable. This knowledge must be

so thorough and complete that the architect can use those forms with perfect ease and precision, and know them as familiarly as he knows the size of a brick or a flue. I said a competent knowledge of some of these forms, and probably no man has known, or can ever know, them all, nor is it necessary. Enough to enable a man to design in one style and to make the detail drawings and profiles for the building is the minimum. How much more is desirable I dare not attempt to say. Possibly the most successful designers have not gone beyond one style; at any rate, the best designs that the world has seen belong to ages when only one style was known and followed in one place. He who would limit himself to one style, however, should at least know every part of that style thoroughly; and he will be helped by that knowledge if he study others. This sort of knowledge of architectural forms and features can hardly be obtained except by measuring and drawing existing buildings themselves. A thorough, accurate, serviceable mastery of one style, such as enables an architect to deal with it as the clothing of his architectural ideas is got nowhere and nowhere except by definite study of existing work, certainly not from photographs, and only partly from drawings, engravings, or books. A knowledge of the history of the art, on the other hand, is obtainable best in the classroom and the library.

We will now try to form an idea of what is meant by a profession, and, as is not infrequently the case, we may perhaps be aided by looking back a little to the days of our forefathers, when life was less complicated than it is now. A hundred and fifty years ago four professions, and I may safely say four only, were generally recognised, though even then one other, to which I will allude directly, might be added. The Services, the Church, the Law, and Medicine are the four. If for a moment we consider what distinguishes these pursuits, we shall have made out the general idea of a profession. First, in each of them there is the idea of some special cultivated skill—in other words, the mastery of an art. The first qualification for a profession is then what is meant by the title. The professional man professes that he is master of an art—in other words, skilled in a certain pursuit. Next please note that each of these callings is pursued on behalf of some one else. The respect in which the professions are held springs from these two qualifications. A man who can do something difficult, and who can accomplish for us what we cannot do for ourselves, is more or less looked up to, and the station that he occupies is held to be honourable. Nor is this honour very seriously impaired, if at all, by the third point of a profession—namely, that it is at once the means of living and also the way of life of him who practises it. The man who does the same sort of work that a professional man does without making his living by it is discredited by the epithet "amateur," which always carries with it a kind of sense of the second-rate, and nowhere more so than when building is spoken of. It is necessary to add that in many cases the practice of a profession includes more or less of what is known as business—that is to say, of acquaintance with, and exercise of, the methods by which serious affairs involving property and money, loss and gain, should be conducted. Every pursuit by which a man seeks to make his living requires some business habits and aptitude of him; but in many professions the very nature of the work done calls for business training and talent. Think of the large pecuniary interests which an engineer has to deal with, or an actuary, or a barrister, and you will recognise that many sorts of professional men are bound to be men of business. Lastly, a profession is the mode of life of the man who practises it, as well as his means of living. If he be not, at least for a period of his life, given up to it, and absorbed in it, and devoted to it, not only is his success in it very problematical, but his claim to any distinction it can confer is doubtful. We have thus arrived at three characteristics of a profession—that it implies the mastery of an art, and of the knowledge needful for its exercise; that it is exerted on behalf of others; that sometimes it is of the nature of a business, and that it is paid. A certain precision might, perhaps, be added to our notions by some negative characteristics. It is not commerce, it is not manufacture, it is not agriculture, and it must not be trivial or mean in the objects to which it summons the professional man to

devote his life. Just as, had I gone further back, we might have come upon a period when in Europe there were but two recognised professions, the Church and the Army, so, by coming nearer to our own time, with the rapid increase in wealth, population, activity, and knowledge which the present century has witnessed, we find one calling after another conforming to the criterion given above, and so added to the list of recognised professions. For example, at least from the days of Reynolds and the establishment of the Royal Academy, a painter has been recognised as a professional man. Since the days of the elder Brunel and Smeaton, the calling of a civil engineer has become a definite profession, and now the list of professions includes literature, education, the fine arts, and not a few of the applications of science, such as the work of the electrician, the consulting chemist, the metallurgist, and many others. But before the days of the earliest recognition of scientific or even of purely artistic professions in England, we have evidence that the architect was a recognised professional man. All that we know about the career and standing of Inigo Jones, of Sir Christopher Wren, of Sir John Vanbrugh, and their colleagues, seems to show that they must have held a position of the same sort as was accorded to the physician or the highly-placed clergyman of the same date, and certainly that they worked as a professional man does now. So that I am disposed to claim for architecture that in England it was the very earliest profession (next to the famous four) to receive general recognition. However that may be, architecture as practised, and as you will have to practise it, is a profession with all the marks of one. That it includes the mastery of an art, and the possession of the knowledge necessary to the exercise of that art, I have endeavoured to show. It is exercised on behalf of a client; it is exercised as the pursuit of a lifetime and as a means of living. It does not relate to mean or unimportant things, and it is not commercial, or agricultural, or manufacturing; but it does require business habits and an aptitude for transacting affairs. If, then, you are to become architects you are to embrace architecture as the one chief work of your lives; and to fit yourselves for the practice of architecture you are to master alike the art, the science, and the profession. And on no other terms can architecture be done, because architecture is building, and building, though no mystery, involves so much that is technical in its artistic, its scientific, and even its business aspect, that in no other way than by becoming a professional architect, and devoting the time and energy which the profession claims, and attaining the skill and acquiring the knowledge which the profession demands, can you hope to execute even an approach to good architectural work.

I conclude by a few words devoted to showing how you are to attain your aim. First—for the practical part of the art, using that phrase to signify chiefly skill and experience and business aptitude, you must look to the practice of the offices where you work as pupils or assistants. Architecture is a very practical profession, and it is of no use to expect that you can learn how to conduct it by attending classes or reading books, or in any other way than by taking as large a share as you can in the work of some office, and watching keenly and observantly all that goes on there. In your office-life nothing is too insignificant or apparently trivial to be unworthy your notice. At the same time, your wise course is to do your very utmost to qualify yourselves for the more difficult parts of the work. Always welcome a difficulty. If a hard master, it is an invaluable one. Beyond this there is the science of architecture, of which you can learn little in an office, but much in classes and from books. And in acquiring the science always, from the first, give prominence to that side of it which has to do with architecture as a fine art. Begin by learning to draw, and to draw well, and then exercise yourselves continuously in drawing architectural objects and other objects partly from other drawings, but as far as possible from existing buildings and from plaster casts, and you will gradually acquire that sort of knowledge and that sort of skill which are at once the most valuable and the most difficult. Early try to get a mastery of perspective, and keep up and extend any skill you have in drawing the figure and in landscape. In addition to this knowledge of forms, which is largely to

be learned by the use of the pencil, gain a knowledge of construction, of materials, and putting them together, and of all the scientific and practical subjects which bear upon your future career. In this, of course, classes, lectures, and books are indispensable, but a good deal can be learned by an observant man from the working and other drawings in progress in the office where he is employed, and more, and that of the most valuable description, on the scaffold or in the workshop. Every student should learn also the history of architecture. As students become familiar with the way in which buildings are shown geometrically, it is very desirable for them to try their hand at designing—i.e., putting together the materials of an artistic and practical sort which they have begun to accumulate in their memory. In this way the rudiments of the highest part of architectural art—namely, architectural fine art, are begun to be mastered. The most valuable school for the study of this, the highest part of architecture, is, beyond doubt, the study of existing buildings. I take it for granted that any student now seriously proposing to become an architect will set before him the passing of the examinations established by the Institute as part of the career which, as a beginner, he must look forward to. Remember that these and the certificates they earn, like all examinations and honorary distinctions, are valuable as means—not as ends. They set before you objects of study. They supply a means of testing what progress you have made, and they supply what is often invaluable—a stimulus; but the object of a student of architecture is to make himself an architect, and that object is not necessarily attained when the first, or the second, or the final examination is passed; nor is it wise to regulate your studies only by the question of whether they will or will not count for marks at Conduit-street. It may not be out of place to point out shortly what subjects can be studied in this college. The history of architecture, looked at as a fine art, forms the subject of one of my two principal courses. Materials and construction form the subject of another course of my lectures, and here each important building material is taken up in turn, its qualities, excellences, and defects are set forth, and the use to be made of it in building is explained. A third course, on the practice of architecture as a profession, touches on the routine of building operations, the laws relating to building, and similar matters as to which an architect should be informed. We have now established, in this college, at the expense of the Carpenters' Company, two evening classes for drawing—one for architectural drawing, and the other for the drawing of building construction—and these, I hope, as they become generally known, will be of great service to many students, for they are calculated both to afford knowledge and to give practice in draughtsmanship. They are under the direct care of two extremely competent gentlemen, as well as under my own general supervision, and the City Company, which has established them, has enabled us to make the fees extremely moderate. These classes all meet at hours calculated to suit the convenience of students engaged in offices during the day. Various classes in this college also afford opportunities for the study of many subjects which it is well for an architect to know, such as geometry, physics, building materials, sanitary science, land surveying, and, in another branch, architectural ornament. I do not wish to conceal from you that the profession is laborious, and that its great prizes fall to very few; but I maintain that its more modest rewards are within the reach of many; and if one among you really becomes equal to the performance of some special feat of architecture, I feel sure that—if not the 19th—the coming 20th century will afford him the occasion for distinguishing himself, and adding to the adornment of his country.

VENTILATION.

MR. E. H. SHORLAND, of St. Gabriel's Works, Erskine-street, Manchester, has sent us a copy of a new illustrated catalogue of his various patented warming and ventilating appliances, which he has just published. It is in book form, and contains over 60 pages, is printed on glazed art paper in bronze ink, and is altogether got up in a first-class manner. The catalogue is divided into three sections—viz., Manchester Grates, Ventilators, and Manchester

Stoves. A novel feature is that the ventilating section, which is in the centre of the catalogue, is printed on pink toned paper (the others being on white), which separates the three sections, and makes it very easy to turn to any one of them. We notice many new designs amongst the well-known warm-air ventilating Manchester grates; these grates being made in almost any design, from the plainest to the most ornamental and costly. Those with canopies have the warm-air chamber projecting well forward over the fire, thus greatly increasing their radiating powers, and are called the new *projecting* Manchester grates. Those without canopies have the warm-air chambers also inclining forward, but not at so great an angle. In the Ventilating section, there are several new designs of both inlet and outlet ventilators, and we notice that all the exhaust roof ventilators are made of galvanised rolled steel, painted with enamel paint.

The patent warm-air ventilating Manchester stoves are shown in a variety of designs, with tiled and iron sides, and both with ascending and descending smoke flues, also single and double fronted. We specially notice the large number of hospitals throughout the country which are heated by the Manchester stoves with descending smoke flues, and the highly satisfactory opinions of their action given by eminent architects and the medical faculty.

throughout the establishment, and can here be seen in process of manufacture.

In the iron foundry there are three cupolas, two of about three tons capacity each, and one of seven tons. There are two overhead travelling cranes, one 15-ton hand gear and one 10 ton, driven by square shaft running the full length of the shop. About 40 tons of castings are turned out per week. The brass foundry and copper-smith's shop adjoin the iron foundry. In the boiler shop there are six overhead travelling cranes driven by flying ropes. The greater portion of the riveting is done by means of two fixed and four portable hydraulic riveters, worked by special pumps and accumulators, two of the portable riveters being specially designed for foundation and fire-hole rings. A large punching press for engine frame-plates 1½ in. thick was seen at work, also horizontal and vertical plate-bending rolls. In the flanging shop there are two hydraulic presses for flanging and stamping plates, worked at a pressure of about 1,600 lb. per square inch, giving on the 20 in. ram of the large press a total pressure of about 220 tons. Boiler, firebox, and other plates connected with engines and tender work are flanged here. The plates are lifted by a specially-constructed crane, and are heated in a gas furnace, the gas being supplied from Wilson's Patent Gas Producers, of which there are four outside the shop, two being in use at a time. Six other furnaces are also supplied with gas from these producers. In the steam hammer shop, stamping by means of blocks and dies was seen carried on to a large extent. There are four gas furnaces which are supplied with gas from the Wilson's Producers; an extra heat per day is got out of these furnaces as compared with those heated with coal. In the smithy was seen the forging of the various parts required in a locomotive, also machines for making rivets, bolts, and nuts. In the wheel shop there are two powerful hydraulic presses for pressing the wheels on and off the axles; these are worked by pumps which give a pressure on the ram of 200 tons.

In the carriage department were seen, in course of construction, four first-class saloons, and 30 third-class suburban carriages, and in the saw-mills some of the best and most improved machinery for cutting up, planing, moulding, and preparing the wood, ready for the use of the carriage and van-builders. There are also machine, fitting, and smith shops in this department.

The wagon department also has extensive saw-mills, and in the wagon shop were seen about thirty 10-ton coal waggons and thirteen cattle boxes in course of construction. Near here is a shop for the manufacture and repairs of carriage and wagon wheels. In the boiler-house attached to the wagon department saw-mills are three stationary boilers of the locomotive type, fitted for burning liquid fuel in combination with solid incandescent fuel. Close by is an oil gas-works in connection with train lighting. After generation, the gas is washed on its way to the gas-holder, and then compressed into cylindrical holders to 11 atmospheres. There are five of these holders in use, each capable of holding 12,500 cu. ft. of gas. The receivers on the carriages are charged to a pressure of seven atmospheres. The average amount of gas made in winter is about 160,000 cu. ft. per week at atmospheric pressure, and in summer about 80,000 cu. ft. per week. The boiler which supplies steam for working the compressing engines burns, as fuel, the tar which is a by-product from the manufacture of the gas. Liquid fuel is also used in the boiler shop for two of the rivet furnaces; the rivets are heated quicker than with coal furnaces, and are not scaled to such an extent. The furnaces are also heated to the required temperature in much less time, and the heat is more under control. The same system was seen as applied to locomotives in combination with solid incandescent fuel.

THE PLUMBERS' COMPANY AND THE NEW LORD MAYOR.

AT the quarterly meeting of the court held at Guildhall last Friday the following officers were severally sworn into office for the year ensuing:—Master, Mr. Alderman Stuart Knill (Lord Mayor elect); warden, Mr. W. H. Bishop; renter-warden, Sir Philip Magnus, B.A., B.Sc. The new master will doubtless earn the

respect of the craft as its chief officer in as high a degree as he has won public esteem by his straightforward manliness as regards his religious opinions in connection with his election to the chief magistracy of the City. We herewith give a portrait of the new master of the Plumbers' Company and Lord Mayor elect. Alderman Stuart Knill, is the only son of the late Mr. John Knill, of Fresh Wharf and Botolph Wharf, and was born at Camberwell in 1824. He was educated at the Blackheath Proprietary School, and afterwards at the University of Bonn, where he graduated. He is now the head of the firm of Messrs. John Knill and Co., wharfingers and warehouse keepers. He married, in 1850, Mary Anne, daughter of the late Mr. Charles Rowland Parker, solicitor, of Greenwich. He resides at the Crosslets, in the Grove, Blackheath. In 1845 he took up his freedom in the Goldsmiths' Company, and is also a member and master of the Plumbers' Company, in whose movement for

ALDERMAN STUART KNILL, LORD MAYOR ELECT.

the registration of plumbers he has taken great interest, and of the Gold and Silver Wyre Drawers' Company. In 1885 he was unanimously elected Alderman of the Ward of Bridge, in succession to Sir Charles Whetham. He is a justice of the peace for the counties of London and Kent, and was long a member of the Greenwich Vestry and District Board. As already indicated, he is a leading lay member of the Roman Catholic Church, and in politics a staunch Unionist and Conservative. He is a member of several learned societies. He is a large employer of labour at his wharves near London-bridge.

THE A.A. "BROWN BOOK."

THE annual "Brown Book" of the Architectural Association has just been published, and shows little variation from that of last year, except that the lectures and classes are now enumerated under four divisions instead of in as many years. The committee in their annual report, which is very guarded in its tone, state that the results of the new scheme of education, which was started during the year, have been, on the whole, encouraging, though, as they admit, "there are many difficulties requiring careful consideration and adjustment which are necessarily attendant upon the launching of such a comprehensive scheme." The premises at Great Marlborough-street, although cramped in accommodation, have answered the purpose as well as could have been expected without unduly hampering the funds of the Association. Turning to the progress of the new scheme, it is noted that the first and second year's courses have been well supported, while the third year's courses have been thinly attended, and, owing to lack of students, part of the fourth year's course was not started. The success, financial and otherwise, of the first two years is encouraging. The committee point out that although the subscription and entrance fees have been doubled, 98 new members have been elected during the session; but on referring to the rolls of membership, we note there has been a slight decrease, the total number being now 1,125 against 1,137 last year, and 1,129 in 1890-91.

A curious sentence in the report states that "The Session has been marked by much animated discussion as to the methods of architectural education, and the Association has been favoured with considerable criticism." During the session an address was given by the President, Mr. F. T. Baggallay, and papers were read by Messrs. W. H. Bidlake, C. H. Brodie, H. Wilson, T. Graham Jackson, J. Garnett, N. H. J. Westlake, Maurice B. Adams, Max Clarke, J. A. Gotch, E. A. E. Woodrow, H. Townsend, and C. R. Ashbee.

The following is the syllabus of meetings for the session:—

- Oct. 7 (To-night). Opening Conversazione at the Imperial Institute.
- Oct. 21. Annual Meeting; address by the President, H. O. Cresswell.
- Nov. 4. "Notes on the Application of an Architectural Education," W. Young.
- Nov. 18. "Some Mysteries of Modern Architecture," Paul Waterhouse.
- Dec. 2. Subject to be announced.
- Dec. 16. Subject to be announced.
- Jan. 13, 1893. "The Influence of Byzantine Art in Italy from the 6th to the 12th Centuries," R. Phené Spiers.
- Jan. 27. "The Small Suburban House," Sydney Vacher.
- Feb. 10. "The Value of Criticism," C. J. Tait.
- Feb. 24. "Individuality and Originality in Art," A. E. Street.
- March 10. "Screens: their Treatment and Symbolism," G. H. Fellowes Prynn.
- March 24. "In Praise of a Country Practice," J. A. Gotch.
- April 14. Members' Soirée.
- April 28. "Hygiene in its Application to the Arrangement of Buildings," P. Gordon Smith.
- May 12. Subject to be announced. E. Guy Dawber. Nomination of officers.
- May 26. "The Travelling Student's Notes," by T. A. Sladdin. Election of officers.
- May 31. Annual dinner.

CHIPS.

A new branch bank at Aston Cross was opened on the 27th ult. by the Birmingham District and Counties Banking Company. The premises comprise a banking-room (22ft. by 21ft.), private-room, strong-room, and a residence for the sub-manager. The building is three stories in height. The front is of Ruabon red bricks, with dressings of Hollington stone to the lower story, and of terracotta to the upper portion. Messrs. James Smith and Sons, of Great Tindal-street, Birmingham, are the builders, and Mr. Cooper Whitwell, of Cannon-street, in the same city, is the architect.

The Medical School wing of Bristol University College was opened on Monday. It forms the first portion of the chief front of the College, and has cost £7,000. The walls are of red Pennant stone, with Bath-stone dressings. On the first floor, reached by a wooden staircase, are the library, laboratory, and lecture-room. The internal woodwork is throughout of pitchpine. Mr. F. Bligh Bond, of Corn-street, Bristol, is the architect, and Mr. G. Humphreys, of Stapleton-road, the contractor.

The Roman Catholic Bishop of Liverpool laid, on Sunday, the foundation-stone of a new school-chapel for the rapidly-extending district of Denton's Green, St. Helen's. The new building will be erected between Denton's Green-lane and Greenfield-road, will be Gothic in style, and is to be dedicated to St. Thomas, of Canterbury, to whom the neighbouring old Windlesham Abbey is also dedicated. Messrs. Sinnott, Sinnott, and Powell, of Liverpool, are the architects, and the tender of Mr. James Almond, North-road, St. Helen's, has been accepted at about £2,000.

Mr. D. Sutherland, timber merchant, of Pulteney Town, N.B., was returned on Saturday at the head of the poll at the election of commissioners for that burgh.

At the parish church of Deuling, Kent, on Sunday, a new reredos was unveiled. It is decorated in style, and constructed of oak, having three crocketed canopies inclosing panels of glass mosaic. Mr. E. P. Loftus Brock, F.S.A., was the architect, and Mr. P. J. Cooke, of Kennington, executed the work.

The work of re-erecting Alfred Stevens's monument to Wellington in a bay on the north side of the nave of St. Paul's Cathedral is progressing steadily. It is not complimentary to the English nation to learn that £300 is still wanting to defray the cost of the removal. Sir Frederick Leighton and the Dean of St. Paul's are the treasurers. The work of the completion of the monument by the addition of the originally intended equestrian figure, according to the approved design, is postponed until the removal and re-erection on the site in the nave originally desired by Stevens is finished, and the expense defrayed.

By 1,295 votes against 369, the ratepayers of Gravesend have resolved to adopt the Public Libraries Act.

PREMIATED DESIGNS FOR THE PROPOSED MUNICIPAL TECHNICAL SCHOOL AT MANCHESTER.—THE CARNEGIE FREE LIBRARY, AYR.—PROPOSED MISSION CHURCH, BLACK HEATH, WONERSH, GUILDFORD.—HOUSES AT BOOTHAM, YORK.—STATUE OF THE GREAT ELECTOR, BERLIN.—FIRE-ENGINE STATION, GRAYS.—TYPES OF OLD ENGLISH FURNITURE FROM WINCHESTER.—SIXTEENTH-CENTURY FRENCH ARMCHAIRS.

Our Illustrations.

MANCHESTER TECHNICAL SCHOOL COMPETITION.

THE first, second, and third premiated designs have been published in our pages during the past fortnight, and we give to-day in completion of the series, the plans and elevation of the fourth prize design by Mr. Theodore Sington, of Manchester, whose façade is intended to be erected in red brick and terracotta. The general arrangements are shown by the two principal floor plans. The other elevation herewith printed is by Messrs. Spalding and Cross, and illustrates the principal front of the chosen design, of which the perspective view and plans appeared in the BUILDING NEWS for Sept. 23rd.

CARNEGIE FREE LIBRARY, AYR.

THIS building, which is being erected from the designs of Messrs. Campbell Douglas and Morrison, architects, Glasgow, is now approaching completion, and from its prominent situation, looking down Cathcart-street and along the new bridge, does not fail to arrest attention. On the principal floor, which is 6ft. above the street level, are placed the lending library, general reading-room, and committee-room, &c. The upper floor is occupied by the reference library, ladies' reading-room, and the museum, or picture gallery. In the lending library there will be accommodation for 25,000 volumes, and in the reference library 5,000 volumes. The basement floor is 3ft. below the street level, and is occupied by the heating chamber, book stores, workshop, lavatory, &c. The librarian's house is in the north wing, on two floors, between the street level and the floor of the museum. With the exception of the reading-room, the floors are all of fireproof construction. The mason-work is built of red stone from the Ballochmyle quarries. Internally, various descriptions of tiles are used on the floors and walls. In the museum and picture gallery the principal part of the walls available for pictures is being constructed with curved surfaces, similar to what has been found so admirable in the new picture galleries, Dundee. The estimated cost amounted to £7,600, and as far as is apparent, the building will be completed within the sum. The memorial stone was laid on Wednesday by Mrs. Carnegie.

MISSION CHAPEL AT BLACK HEATH.

THE mission chapel and school-room at Black Heath, Womersh, Surrey, is intended to accommodate about 180 people. The exterior has been purposely kept simple, and without smallness of detail, and reminiscent of the small wayside

chapels in Tyrol and North Italy, where effect is sought entirely by proportion and colour-treatment. The concrete walls are roughly plastered externally, and distempered a warm tint, and the arches to the windows, &c., are of specially-made bricks of a deep red colour. The interior is to be painted throughout with figure subjects. Messrs. Brown, of Bramley, are the builders, and the architect is Mr. C. Harrison Townsend, of 29, Great George-street, Westminster.

HOUSES AT BOOTHAM, NEAR YORK.

THE original drawing herewith reproduced was shown by the architect, Mr. Arthur S. Jones, A.R.I.B.A., architect, of Chelsea, at the Royal Academy this year. The two plans carefully show how a variety of treatment has been obtained by bringing one entrance out of the return street and a picturesqueness of planning secured by cleverly adapting the special limits imposed by the irregular line of the site. Timber, stone, brick, and tiles combine to produce an artistic effect.

STATUE OF THE GREAT ELECTOR, BERLIN.

THIS group, from the hand of Andreas Schluter, the contemporary of Grinling Gibbons the Dutchman, stands on the Long Bridge near the Castle and the Schlossplatz, in the heart of Berlin, overlooking the Spree. The equestrian statue of the Great Elector, Frederick William, is executed in bronze, and represents the rider garbed in the capacious folds of a Roman toga, riding with dignity and serene magnificence, after the fashion of the Rococo period. It possesses considerable merit as a work of art, notwithstanding the redundancy of the composition. This reaches its climax here perhaps in the treatment of the chained figure nearest the spectator, where the right foot rests upon a helmet, and the other, beyond the confines of the lower step, is placed on some specially-concocted drapery extending to the pavement. The freedom of the general lines of the pedestal and the details of the group as a whole are eminently characteristic of its date (1703), but the pleasing breadth and sense of scale which governs the general conception compares very favourably with the paucity of design and feebleness of idea so often conspicuous in similar works of more recent date. Berlin itself supplies a notable instance of this in the much-belauded statue of Frederick the Great, modelled by Rauch at the cost of the Government in 1851. The granite pedestal in three stages is surrounded by bronze groups serving as a frieze, illustrative of the great military commanders of the Seven Years' War, on foot and horseback, all to life-size and portraits. The Emperor himself is represented in the habit of his daily life, copied in minute particulars and enlarged to heroic size, as the statue itself is 17ft. high. Capital as the individual features may be, the outline of the whole is petty and poor as contrasted with Schluter's work. We have reproduced our illustration, by permission, from the first part of a splendidly produced new folio on the "Statues of Europe," issued by the indefatigable Herr Von Ernst Wasmuth, of Berlin, who, under the title of "*Monumente und Standbilder Europas*," is grouping together a series of specially taken photographs from all parts. If the whole compare in excellence with those contained in the opening selection, the work must be of universal interest. In the present book, besides photographs of the two statues already mentioned, we have Baron Carlo Marochetti's Richard Cœur de Lion (1854) in Old Palace Yard, shown by a very artistic photograph, with Henry VII. Chapel and St. Margaret's Church in the middle picture. A lad well placed brings out the scale and high light of the pedestal capitol. The Albert Memorial, by Sir Gilbert Scott (1870), is the other London example. From Paris figures the Vendôme Column (1806), and from Vienna Marchesi's Kaiser Franz I., erected in 1846, the Archduke Charles near the Burgthor (1859), and the Maria Theresa Monument, put up in 1883, so that the work is brought down to contemporary productions. St. Petersburg furnishes Falconet's prancing Peter the Great (1782), and from Copenhagen Christian IV., dated 1810, by Thorwaldsen. The plates measure 19in. by 12in., and are printed by the colotype process.

FIRE STATION, GRAYS.

THE growing little town of Grays, on the north bank of the Thames, about 20 miles from London, has been for some years now a home of the

Portland-cement trades, and of the manufacture of the so-called "London Stocks," which, in spite of all the advancements of machinery, continue to be hand-made to-day in precisely the same way as Daniel de Foe made bricks at his historic tileries at Tilbury, close by. One of the old institutions of the place is its volunteer fire brigade, and it has been needed, and in its time, even quite recently, has performed some signal services. Mr. J. Theobald, M.P., the lord of the manor, having granted a site to the local board, their surveyor was instructed to prepare a scheme and a plan, and a loan of £1,500 has been sanctioned. The building is designed for the accommodation of the equipments of a first-class brigade, with a drill-room on the first floor, and a drill-yard in the rear. As the newly-fledged board does not as yet possess a fire-steamer, but owns and uses the more common-place appliance of a steam road-roller, the latter machine will, for the present, make use of the engine-house with its necessary pit in the floor, and its telescopic funnel to slide into the ordinary chimneys. An attempt has been made in the building to enhance the effect of modern Queen Anne by harmony of colour, the light cream of ordinary stone being relieved by selected common London stocks, with the gables of the natural bluish grey of carved Portland cement, the carving, needless to say, executed in its plastic state and with plenty of undercut, an art as yet in its infancy, the result, by a judicious selection of cement, and the absence of other manipulation, being expected to be equal in durability to ordinary Portland stone. A local red brick is also introduced. The design, as now illustrated, was exhibited in the Royal Academy, and is being carried out by Mr. W. H. Archer, of Gravesend, with Mr. Wm. Wilks, as sub-contractor for masonry, under the supervision of Mr. Charles Cobham, F.S.I., the local board's surveyor and architect.

FRENCH ARM-CHAIRS OF THE 16TH CENTURY.

THE rare character of these four chairs from the Louvre makes them especially interesting on this side of the Channel, as seldom, if ever, are their counterparts to be seen in our country. They all express quiet dignity, more particularly perhaps the last on our sheet, with the quaint entrance rendered in perspective with different coloured woods. The seats, like some of our early chairs, are V-shaped on plan, two of them being treated in the usual way with four legs at the angles, the other two having a central support carried on three spreading feet, somewhat suggesting the music-stool. Our sketches were made from plates in "*Le Moniteur des Architectes*."

CHIPS.

Sir T. D. Gibson-Carmichael, Bart., has intimated his intention of presenting to the Selkirk Free Library Committee full-sized copies in bronze of the famous "Resting Mercury" in the museum at Naples, and also of the "Adorante"—perhaps the two most beautiful specimens of Greek bronze sculpture which have hitherto been found. The bronzes, which are from piece-moulds of the original, are already on their way.

A medallion head of the late Dr. Alexander Kilgour, which has been executed by Mr. John Hutchison, R.S.A., Edinburgh, is to be placed in the Aberdeen Royal Infirmary.

Mr. Joseph T. Firbank, the well-known railway contractor, who contested the Haggerston Division of Shoreditch in the Conservative and Unionist interest at the last election against Mr. W. R. Cremer, M.P., was presented on Monday at the Haggerston Constitutional Club, Kingsland-road, with an illuminated address.

Under initials which thinly veil the name of Mr. Walter Millard, a letter appears in Tuesday's *Times* mentioning that No. 7, Delahay-street, Westminster, once the residence of the notorious Judge Jeffreys, is now in process of demolition. The house itself, Mr. Millard adds, "is well worth inspection as a good specimen of what is now a rapidly-fading type of Domestic architecture. The spacious, dignified staircase and entrance-hall is calculated to send a shudder through the designers of our modern pinched and skimpy dwellings."

The Accrington town council sanctioned, on Monday, a scheme for purchasing land for the erection thereon, at a cost of under £10,000, of an electric lighting station to supply the town with the electric light. The corporation have also under consideration the purchase of the gas and water-works for £700,000.

Types of Old English Furniture.

From the Stores of Messrs Thomas & Co.
Winchester.

SKETCHES OF OLD FURNITURE.

THE accompanying sketches serve to illustrate some types of furniture made in England up to the beginning of this century. The art of cabinet-making in this country was carried on with as great skill, and, as a rule, in more refined and less extravagant styles, than in any country abroad. The oldest pieces illustrated are the quaint oak Cabinet with the Elizabethan or Early Jacobean ornamentation of halved turned work planted on, and the elaborate mitrings of mould-

ings in panels, and the fine old Sofa with carved oak rails connecting the square bow legs, which came originally from Shaw House, near Newbury, and was picked up in a broker's shop and "restored" from an almost shapeless ruin. The rarest piece of furniture is the painted Couch of the Hepplewhite school (in 1770) from a village near Winchester. The sketch gives the design of the woodworks but little idea of its appearance, as it is painted all over with lilies, pine apples, &c., in quiet colouring on a sage-green ground. It has a look of too great

fragility, but is very strongly constructed of beech and ash, every joint being beautifully bound and tenoned together. The Chairs are examples of the more ordinary types of the last century, and show what beauty of design and careful thought was exercised in the treatment of the backs. They are made of the now extinct Cuba or Spanish mahogany, very heavy, and of dark colour and fine grain, which was in such demand in the time of Sheraton, Chippendale, and their followers, that the supply became entirely exhausted.

FRENCH ARM-CHAIRS OF THE SIXTEENTH CENTURY

WAYSIDE NOTES.

THE uncertainty regarding the genuineness of the so-called "Garden Tomb" at Jerusalem makes the sum of £4,000 a decidedly heavy price to pay for its acquisition. Supposing that a tomb of undeniable identity were forthcoming, one can imagine any sum being paid and subscribed by enthusiastic persons. As it is, would-be subscribers hesitate, and this is certainly well. There can never be any good effected by purchasing things of hypothetical interest. More probably harm is done, and people led to the belief that that is which is not.

Many writers of experience in matters of Biblical interest in Palestine and Jerusalem have stated their reasons for not giving credence to the theory. Unfortunately, the late General Gordon having pronounced in favour of the probable authenticity of the tomb, the public, with a natural reverence for all thoughts and actions of that great soldier, have exhibited a blind faith in his views as to the question in debate. This is calculated to lead to an enthusiastic impetuosity in the matter of purchasing the tomb. Far better is it to leave the uncertain in uncertainty. Faith is one thing; a positive view in matters of uncertainty is another, and persistence therein neither productive of good in the present nor future. When due season arrives, let the spikenard be bruised; until then the perfume should be husbanded. Four thousand pounds in charitable works seems more in accordance with the spirit that breathes over the subject than any expenditure on a tomb of doubtful identity.

Missionaries who do not respect the ancient usages, and even minor superstitions and prejudices, of the peoples among whom they work are not likely to effect much good. From a paragraph in the *Times* regarding missionaries and tall buildings in China, I learn that much offence is given to the natives by reason of the height to which the missionaries carry their buildings, either residences or churches. The Pekin correspondent of a Shanghai journal says that the Chinese dislike buildings of many stories, it being their idea that the privacy of their own dwellings is invaded by the practice. They accordingly remove from the proximity of such buildings. Yet all over Pekin, it is said, mission stations are easily recognised by their large upper stories. As the houses near such places are deserted, the landlords are greatly injured, being obliged to sell their premises at a great loss to the mission stations. Chimneys, too, seem a great cause of offence, especially when they confront a native whenever he opens his door, while verandahs overlooking the courts of native houses are sources of serious objection. It appears that the Roman Catholics have been great offenders in erecting high churches, dominating all the houses around. When the Peitang or northern cathedral in Pekin was built, it overlooked the precincts of the Imperial Palace, and was long an eyesore to the people. At first it was sought to shut it out by erecting a huge wall, and at length was, after long and troublesome negotiations, bought by the Empress-Dowager, and inclosed in the Palace grounds. The correspondent further says that an epidemic of building upper stories has seized the missionaries in Pekin. He also says that Sir Frederick Bruce was opposed to missionaries visiting Pekin. After they came, he advised them "to conduct their operations in a quiet, unostentatious manner, and to begin their services in the lanes in native buildings."

It may seem foolish enough here, where everyone overlooks someone else, but to ride roughshod over native prejudice is scarcely judicious, and certainly ill-becoming in missionaries. As a matter of fact, excessively high building does give offence even in this country, and doubtless the Pekin mission-stations are, to the Chinese native, houses what Hankey's Folly and other "sky-scrapers" are to the average London building. In any country the erection of buildings far in excess of the average height is—properly considered—an offence to society. One would imagine, therefore, that the builders of obnoxious buildings in China would have desisted as soon as they found their practice objectionable, and that they were not "becoming all things to all men" like the first apostle to the Gentiles. Respecting Sir Frederick Bruce's requests of the missionaries, the correspondent of the Shanghai journal says:

"If there was room for this wise advice immediately after the war, how much more now, when China is scrutinising closely the treaty provisions."

I would that what Lord Rosebery said *re* the dignity of manual labour at the opening of the Borough-road Polytechnic Institute should be taken to heart by many young men now just commencing a mercantile career with small prospect of ever getting beyond the clerkship stage. They should remember that the words are only an echo of what Mr. Gladstone has but recently said, and other great men have urged the same for years. The time should come when the mock respectability that clings to the career of clerkship when in prospect only should fall away like scales from the eyes of "parents and guardians" of humble means. "Mrs. Grundy" unfortunately generally enters most frequently into homes where her presence can least be afforded. The lower middle-class possibly think more of "appearances" than any other persons in whatever stratum of society. To wear a long-sleeve hat and a cut-away coat, with umbrella and black bag to match, being considered necessary to respectability, so many youths are, in consequence, doomed to life-long and miserable drudgery. There is happily just a chance—perhaps a very good chance—of the modern polytechnic institution effecting much good in this matter. In view of this possibility let us hail with joy each institution as it appears.

An article, evidently of American inspiration, in the current *Scribner's* gives statistics concerning the buildings of the Chicago Exhibition. It veritably gloats over the bigness of the things. Take, for example, the rhapsody on the Manufactures and Liberal Arts Building:—It is 1,687ft. by 787ft. in size. It covers about thirty-one acres. The great main roof covers an area 1,400ft. by 385ft., and has an extreme height of 210ft. This is between 55ft. and 60ft. higher than the great arch of the Machinery Building in the recent Paris Exposition. It is only 10ft. less in height than the great chimney of the New York Steam-Heating Company. It is just 6ft. lower than the top of the spire of Grace Church, New York. It is 11ft. lower than the Bunker Hill shaft at Boston. It would hold the Vendome Column mounted on a 74ft. pedestal. The seating capacity of the building is estimated at over 200,000 people. St. Peter's, at Rome, holds about 54,000; St. Paul's, in London, less than 20,000, and the Metropolitan Opera House in New York has a capacity of 5,000 people. The entrances of this building are 40ft. wide and 80ft. high. Its ground plan is much more than twice the size of the Pyramid of Cheops—and so on; but this sort of thing gets wearying.

The L.C.C. look well after theatres as touching any danger of fire and panic. A correspondent of the *Fall Mall Gazette* asks when this authority will look after Exeter Hall. The place is said to be a regular trap. The two doors at the ends of the corridors beneath the galleries *open inwards*—fact astounding and incredible—and these galleries, writes the correspondent, were crowded to excess at a meeting the other evening.

I like analogies. Mr. A. Braxton Hicks, coroner for the Battersea district, as president of the Battersea Amalgamated Evening Classes Swimming Club, said, the other evening, that though the lads were beginning to swim in style, they must remember that the great thing needful is to swim, independently of style. This is excellent. Many persons might remember that the same reasoning applies to design. The great thing wanted is, after all, the building. Often we have plenty of style, and precious little house.

Near Worthing is the interesting old church of Broadwater. It is, doubtless, well known to very many, being in such close proximity to a favourite seaside resort. I had never visited the building until a few days ago. A most peculiar feature is the arch of the crossing opening into the nave. In form it is Early English, in mould and enrichment most beautiful Norman work. It is said to have been formed out of the voussoirs of a round arch, which fell down. The arch opening into choir is an irregularly depressed round arch. I wish enthusiastic

amateurs and archaeologists would refrain from stuffing credulous parish clerks with nonsense respecting these irregular-shaped Norman arches. Our good friend at Broadwater has had someone endeavouring to enlighten him in this way. The fact of the matter would seem to be that circular arches get easily out of shape, and therefore some few years having elapsed since Norman times, many of the arches of 12th-century architecture have become depressed, and thrown up at the haunches. I know that some people hold peculiar views on this subject, and they have now an opportunity to back up their theories in these columns. Personally, I give the Normans credit for being common-sense builders, with an eye for fitness and order, and prefer to consider them superior to the architectural vagaries with which some would saddle them. GOTH.

PRECIPITATION WORK AND SEWAGE DESTRUCTORS AT SOUTHAMPTON.

THE sewage precipitation works at Southampton, carried out from the designs and under the supervision of Mr. William B. G. Bennett, borough engineer and surveyor, are very complete. Messrs. Manlove, Alliott, Fryer and Co.'s refuse destructor has been adopted for destroying the ashbin contents and garbage of the town. This has six chambers or furnaces, each burning eight to eleven tons of garbage a day. The sewage sludge is also transmitted to the destructor from the two reservoirs on the town quay, each of these being 100ft. by 60ft. and 10ft. deep, into which the sewage of a part of the town flowed by gravitation, being discharged at low water. Two of Shone's pneumatic ejectors have been brought into operation to render independent of the tide the discharge of the effluent from the reservoirs, and to raise the low-level sewage into them for treatment. These ejectors are worked by power obtained from the destructor. One of these (36 gallons) is placed below the reverts of the low-level sewer, and serves for transmitting the sludge from the reservoirs to the destructor, as well as for raising the sewage from the same sewer. Another of 700 gallons capacity is placed in the east reservoir for discharging the clarified effluent into the Southampton Water. A third ejector deals with the sewage of another district. Precipitation of the sludge is obtained by the use of ferrozone supplied by the International Water and Sewage Purification Company; it is mixed with enough clean water to make the whole into a stiff paste, which is led through a shoot into a box with perforated sides placed in the sewer, the sewage flowing past washing the ferrozone gradually out of the box. The sludge is mixed with road sweepings or sorted refuse at the destructor, and is turned out as good manure, which is sold at 2s. per load at the works. The amount realised from the sale, and for the supply of compressed air to other ejectors in the neighbourhood during last year, is stated to be £600. The products from the destructor, concrete slabs, clinkers for concrete foundations, and fine ashes, represent about £300. The waste heat from the destructor is used for producing electricity. We have gathered these facts from a paper read before the Institution of Mechanical Engineers at Portsmouth by Mr. Bennett, which contains full details of the ejectors, reservoirs, and destructor, and which is of interest to borough surveyors.

Mr. M'Kenzie, of the firm of Messrs. Matthews and M'Kenzie, architects, Aberdeen, again visited Balmoral on Saturday, and submitted to Her Majesty plans for the proposed new church at Crathie. The Queen was pleased to approve of the plans, and to give them her final sanction. The design of the church is Gothic of an Early Scottish character, resembling in many respects the church of St. Monance in Fife. The south transept will be reserved for the accommodation of the Queen and the Royal Family, and will have a separate entrance.

The Queen's-road Board School at Leeds was opened on the 28th ult. It is on the central hall plan in three departments. The two central halls each measure 77ft. 6in. by 32ft. The classrooms are 16ft. high, and hold 60 scholars each. The total accommodation of the school, inclusive of the central halls, is for 1,236 scholars. The building is built of brick, with stone dressings, and is in the Italian style. The schools have been designed by Mr. William Landless, of Belmont-grove, Leeds. The cost of the site was £2,281 6s. 6d., and that of the buildings and fittings about £12,880.

NOTES FROM PARIS.

THE summer holidays are now rapidly drawing to a close, and those who have been fortunate enough to have left for a time the bustle of affairs in this great city are now thinking of returning to serious work.

As far as the younger aspirants to the architectural profession are concerned, work is already beginning in good earnest; the vacation is over, and those who have been clever enough to have passed the entrance examination of the *Ecole des Beaux Arts* are settling down to the winter's study in one of the various school studios. The private class studios for painting and modelling are rapidly filling up; the evening classes are in full swing, and those English and American art students who have been visiting their homes or doing a trip to classic lands have returned, are putting to rights their own studios, sorting out their studies, and anxious to start on the picture which each one hopes will get a place in the Salon or Academy of next year.

A visit to the studios of the Latin quarter—those large private studios which take their turns as working-room, living, and bedroom, and even drawing-room when occasion calls for it, is most interesting. On his return to work each artist, as a rule, makes a round of visits to his friends' studios for a hand-shake, and a pertinent inquiry as to the ideas of his brother brush for his next great attempt. Some of them work very hard, beginning betimes in the morning until sundown, and then, after dinner, working at one of the class studios for drawing and modelling and life studies. The communal schools are crowded every evening with young fellows, artisans and others, drawing from the model, plaster, or life, or busily working out designs in clay or wax. These classes are free to all, good professors visit them, and a great deal of excellent work is done.

At the *Ecole des Beaux Arts*, the young architectural students who have just been received at the school, and have chosen one of the various studios, are working hard at the elements of architecture, and trying each one his best to carry off a medal or mention at the monthly competitions. They often begin very well, eagerly following the theoretical lecture, and studying hard at the elementary drawings. But, as often, their zeal gradually dies away—first a lecture or two is missed, afterwards many; the monthly competitions are often done hurriedly and at the last moment. In fact, complaints are being made that too much liberty is allowed at the schools, the student working more or less as he pleases. It is true that he would have to work very hard if he wished to follow all the lectures and drawing studies, for many of the younger ones, who may have little or no resources from their homes, are forced to “faire la place,” as it is called, or work for a portion of the day or week at one of the business offices, in order to add to the funds necessary for them to follow their studies and live the student life. The subject of the school study compared with the apprentice or pupil system is at present very much under discussion. Each, evidently, has its merits, and each its disadvantages. The apprentice or pupil who works entirely in an architect's business office has not enough opportunity to pick up ideas—not enough time, unless he is an ardent worker during spare hours, to get up studies and designs for himself. He then often falls into a groove of ideas—he sees only the style special to his master, and thus lacks the readiness and quickness of design so necessary for pressing work. But, on the other hand, he often sees good practical work, has occasional opportunities to visit the buildings during construction, copies or makes out specifications, &c., and follows the general run of the business office.

The student who confines himself wholly to the school studies has perfect liberty, and, if he be studious, will be always present at the different lectures and classes, and work up for the examinations thereon. He works at the drawing studies, either in getting up designs of his own or emulating his fellows in the monthly and fortnightly sketch competitions. He has an opportunity of seeing the designs of his fellow students, the many ideas and styles worked out, is looked over by a good professor, receives and imparts ideas—in fact, goes through the course of mutual teaching in vogue at the studios. But if he is a hard worker, and cares to add to his practical knowledge as well as to his purse, he may work during spare time at an architect's office. He rarely takes a fixed berth; but works

here and there at odd jobs—competition and other work; the payment, as a rule, is by the hour.

Building operations are being carried on to an immense extent at Paris this year, and Parisian architects have not been able to complain of lack of work. To the west of the city the number of buildings put up is remarkable. The immense “immeubles,” or houses let on the flat system, are being rapidly built in this quarter, and how different the style from that of only a few years ago! These massive six or seven-story structures are most imposing, and form the type special to the Paris boulevard or street. The exterior is decorated with a large amount of judiciously placed carving, designed and executed by an artist hand. Mr. Buggins would find very little to do at Paris; his jerry-built, uninteresting work would not suit the public taste. All the modern improvements are introduced into these new houses; the staircases are large and well lighted, and lifts are being extensively used; the floors are always constructed of iron rafters filled in with brick and plaster, and the latest sanitary appliances are employed. A great feature in the exterior of the building is the large square bay window, wholly of iron, with casements filled in with coloured glass. These bays generally mount from the first floor to the topmost story. Mosaic panels and coloured tile decorations form also a special feature. The style of architecture generally seen has become more free for these kinds of buildings; the façade looks massive. The broad pilasters, with well carved capitals and broadly-treated sculptured panels and keystones, make an imposing effect.

The question of sanitary improvements is beginning to occupy a place of great importance at Paris. As a rule in this city, or until a very short time ago, the system of water-flushed drainage is very little employed. The water-tank in the closet is unconnected with any water service, and has to be filled by hand from time to time, and, through neglect, is often left dry. The soil-pipe descends to the basement, allowing the soil to fall into a covered cistern, from whence the matter is pumped at fixed times into airtight vans, and carried away. A certain fee is payable to the company which does this work. If too much water is used to flush the closets, and the cisterns are left full too long, they overflow and inundate the foundations with the poisonous matter, forming, in time, a good lurking-place for infectious diseases. But lately the *tout à l'égout*, or drainage system, has been introduced, the drains carrying away the matter to the river. Only 6,500 houses in Paris employ this system at present. It appears that over 250,000 cube yards of refuse matter is thrown daily into the Seine, turning the river into a perfect drain. Complaints come daily from the sanitary authorities and proprietors of the villages and lands below Paris, setting forth that the river water has become perfectly poisonous and dangerous to the health of the inhabitants of the villages on the banks. A scheme is therefore being discussed to drain the matter from Paris by a system of flushed drains into the country as far as Acheres, where it will be converted, and sold or employed as manure and other purposes. The question of drainage as far as the sea has been renounced as being too costly.

Visitors to the Louvre will have noticed for some time past the heavy scaffolding which encumbers the grand staircase leading to the first floor. This has now been taken away, although the work intended to be done is by no means completed. The intention was to decorate the staircase with marble panels, and to cover the six vaults of the dome with mosaic, representing Antique Art, Middle Ages, Renaissance, and Modern Art. From 1884-87 the mosaists worked at the Renaissance design, containing four large figures and medallions of Poussin, Raphael, Rubens, and Albert Durer. The antique art was then commenced, and should have been completed in time for the 1889 exhibition, but even now it is not far advanced. As, however, the work seemed to continue indefinitely it was decided to remove the ugly scaffolding; the panels of the work remaining to be done will be put together in the studios and then rapidly put into place. Visitors to the Louvre have now the opportunity of admiring the costly work already in place.

They are already talking of the proposed exhibition for the year 1900 at Paris. The site proposed for the buildings is the plateau of Courbevoie, some little distance outside the walls to the north-west of Paris. This was one of the sites proposed for the last exhibition, but for

many reasons it was not thought suitable at the time. Railway and other communication will afford an easy access to the exhibition from the city, and also to the Champ de Mars, where the buildings remaining from the last exhibition will be utilised for minor objects. Ingenious minds are trying to think of a new “clou,” or special attraction, such as was the Eiffel Tower. Certain astronomers propose to construct an immense telescope or mirror which will, they say, bring the moon to apparently a yard or two of the earth. Another idea is that of an immense waterfall, resembling, and even surpassing, Niagara in magnificence. But in the eight years that are before us before 1900, many new inventions may have changed the course of ideas.

The ruins of the Chateau of St. Cloud, so well known to English tourists, are rapidly disappearing before the attack of pick and shovel. These historical ruins, which have become an eyesore to the Parisians, will be replaced by magnificent gardens. The existence of former buildings on the site of the present chateau may be traced back to a very early period in the history of the country, and, like Versailles, some portions of the ancient buildings are preserved in the midst of the later construction. The last building, the present chateau, was completed, as far as the exterior is concerned, about the year 1680. The architects of the time, Lepautre, Girard, and Hardouin Mansart, took part in its execution for the Duc d'Orleans, brother to Louis XIV. Later on it was given by Philip d'Orleans to Marie Antoinette. Napoleon III. made it the summer summer palace of the court. In 1793, during the Revolution, it was declared public property. In 1815 the Prussian Blücher held there his corps de garde. From the chateau the declaration of war against Prussia in 1870 was declared, and on the 13th October of the same year, a fire, originated no one knows how, left the chateau in about the state in which it was in when given over a short while ago to be demolished. St. Cloud will lose a series of picturesque and interesting historical ruins.

ARTHUR VYE PARMINTER.

THE CLEANSING AND VENTILATION OF SEWERS.

AT a meeting of the Society of Engineers, held at the Town Hall, Westminster, on Monday, Mr. Joseph William Wilson, junr., President, in the chair, a paper was read by Mr. B. A. Miller on “The Cleansing and Ventilation of Pipe Sewers.” The author having mentioned the difficulties which had been experienced in many towns sewered on the combined system, owing to the road detritus being washed into the sewers through inattention to gully cleansing, drew attention to the necessity of constant flushing to prevent the generation of sewer gas, due to the decomposition of deposited matter. He then compared the system of combined and separate sewerage, giving the following reasons for preferring the latter:—Smaller sewers are required; surface water drains need not be laid as deep as sewers; the exclusion of surface water gives less liquid to deal with and be treated; there is greater regularity in the flow, enabling the size of sewers to be calculated more accurately; the sewers, being smaller, afford less space as gas-holders, and require less water to flush. He recommended the admission of roof-water into the sewers. He then alluded to flushing, giving the different methods employed. The use of penstocks or plugs, causing the sewage to back up, he considered unsatisfactory, as deposits are left in the pipe to decompose. In preference he advocated the adoption of flushing chambers, containing automatic siphons, mentioning those of Messrs. Doulton, Rogers-Field, Adams and Palmer, and proceeded to describe the action, giving preference to those with a deep trap. Passing to the question of ventilation, he enumerated the different methods employed for ventilating sewers, describing first the usual methods by shafts from the sewer to the street level, with open gratings in the roadway, intended to act as outlets and inlets, but which were often an annoyance owing to the irregularity of their action. The Holman-Keeling sewer gas destructor was considered effective, though costly, and he suggested the erection of iron shafts, either open at the top or provided with cowls, which could take the place of street lamps, placed on the line of kerb, and connected with the sewer. The author then gave a description of a

series of experiments taken in one of these shafts at Beckenham, with a view of ascertaining the advantage of ventilating sewers by ventilating lamp-posts, as compared with the ordinary method of gratings in the roadway. A series of tables and charts showed that the best results were obtained when the street ventilators were open, and, further, that the direction of the wind was the chief agent which influenced the movements of sewer air in the shaft, the temperature also affecting it under certain conditions. He recommended, in order to keep sewers in their proper state, periodical flushing by automatic chambers, and an efficient method of ventilation by ventilating-posts, which would produce a better current of air in the sewers than is obtained by the ordinary methods of street openings alone.

OBITUARY.

M. ERNEST HENDRICKX, of Brussels, one of the leading architects of Belgium, died unexpectedly at the close of last week. He was a professor at the Free University of Brussels, and at the industrial school in the same city, and also lectured regularly in the School of Arts and Design at S. Josse-ten-Noode. Only a few days before his decease M. Hendrickx was announced to have won the competition for the construction of the chief entrance to the Palace of Justice at Brussels.

Mr. William Sinclair, builder, of Lerwick, died on Friday afternoon in his sixtieth year. A native of Shetland, he served his apprenticeship to the joiner trade in Edinburgh, and wrought there as a journeyman some years. In 1860 he returned to Lerwick, and had since carried on business in partnership with Mr. John Hardie, the firm being known as Sinclair and Hardie.

COMPETITIONS.

KEIGHLEY.—The town council of Keighley received and adopted on Tuesday a report by the hospital committee as to the plans submitted in competition for the proposed infectious diseases hospital to be built at a cost not to exceed £4,000. The institution was to provide separate and isolated departments for typhoid fever, scarlet fever, and small-pox patients, with administrative block, and the usual out-buildings. A large number of designs were sent in, and that submitted by Messrs. Judson and Moore, of Keighley and Bradford, was selected.

SOUTHWARK.—The library commissioners of the parish of St. Saviour's, Southwark, having examined the designs sent in by competition for the new public library, have decided on that by Mr. John Johnson, of Queen Victoria-street, E.C. All the designs sent in for competition will be on view to the public from to-morrow (Saturday) until the following Saturday, at the Vestry Hall, Borough Market.

The first of the fourteenth course of lectures to sanitary officers was given at the Sanitary Institute on Tuesday evening by Sir Douglas Galton, on "Ventilation, Warming, and Lighting."

The additions to Mason's College, Birmingham, made at a cost of £20,000, have been opened this week. They consist of medical schools, and have been carried out from designs of Messrs. Cossins and Peacock, of that city. Messrs. W. and J. Webb, also of Birmingham, are the builders.

A cheque for £200,000 was, on Wednesday week, ordered by the Ipswich Corporation to be signed in favour of the Directors of the Ipswich Water Works Company, and on the following day the undertaking was formally transferred to the Corporation.

The reflooring of the nave of Manchester Cathedral is now proceeding rapidly under the direction of Mr. Crowther, the cathedral architect, and it will be so near completion by Sunday week, October 16, that the nave will be reopened on that date for public service.

The new schools at Dame Margaret's Home for Waifs and Strays, Washington Hall, were opened by Sir Lowthian Bell on Monday. The laundry at the Hall has been rebuilt, with the result that a large school and suitable classrooms have been provided at the Home. There will be accommodation in the school and classrooms for 120 scholars. At present there are 81 poor children in the Home. The building has been completed, from designs by Messrs. Plummer and Burrell, of Newcastle-on-Tyne, by Mr. Hunter, builder, of Washington, Co. Durham.

ARCHÆOLOGICAL.

KIRKSTALL ABBEY.—The *Leeds Mercury* says the work undertaken by the Leeds Corporation with a view of preserving this historic ruin is being steadily carried out. It was found that many portions were in an extremely unsafe condition. The services of Mr. J. T. Micklethwaite, F.S.A., of London, were secured, and the work of strengthening the walls was commenced in May, 1891. To erect new walls or pillars, or to replace the vaulting, was not the object which either the Corporate Property Committee or the architect had in view. While desirous of strengthening, they were strongly opposed to depriving the ruins of any of their historic interest. The instructions given to the masons were not to use a single new stone if they could possibly avoid it, but to utilise all the old material lying about the structure. The groining of the south aisle and the adjoining walls have been restored, all the defective joints having been filled up with concrete. A large amount of rubbish has been removed from the north transept, and beautiful features of the fabric have thus been brought to light. Among the rubbish were found many fine pieces of masonry, some of them in a remarkably good state of preservation. One capital discovered appears quite modern, the outline being almost as sharp as it would be on leaving the hands of the carver. A considerable portion of the north aisle was demolished by the fall of a portion of the tower. To strengthen the part of the wall standing, and to increase the stability of the walls of the north transept, two pillars are now being erected. The walls of the north transept have also been tied with wood, and all the joints cemented, so that now this portion of the abbey is perfectly safe, and likely to remain so for many generations. Nothing is at present being done to the tower. The corporation would like to do something to strengthen it, but they foresee the difficulty of erecting scaffolding in such a position, and of doing what else is necessary. At present, however, little fear is entertained as to its safety. The adjoining walls appear to be in good condition, and a stiff breeze would be required to do any damage. A gale from the north-west would be the most dangerous, as the angle faces in that direction. During the frost of last winter a part of the west wall of the cloister fell. This has now been rebuilt with the old stone. With a view of preserving the east vaults, a layer of asphalt has been placed over them. One of the supports of the ancient staircase leading from the cloister to the dormitory gave way last spring. This has been replaced and strengthened with brickwork. This is the only instance in which new material has been used. Nothing, as yet, as been done to the east end of the chapter-house, but it is probable that the top will be strengthened with asphalt. Complaints have been made about the removal of the ivy and foliage from certain parts of the ruins. This has been totally unavoidable.

ROMAN REMAINS IN CUMBERLAND.—The Cumberland and Westmoreland Antiquarian and Archæological Society recently visited Hardknott Castle, in Eskdale, Cumberland, to inspect the excavations which have recently been made, under the supervision of Chancellor Ferguson, F.S.A., president of the society; the Rev. W. S. Calverley, and Mr. C. W. Dymond, by which the principal features of the Roman camp there have been revealed, and a number of Roman relics discovered. Hardknott Castle, which is referred to in one of Wordsworth's sonnets as "that lone camp on Hardknott's height, whose guardians bent the knee to Jove and Mars," is about three miles from the well-known hostelry, the Woolpack Inn. The President read a paper, in which he described some of the scenes which would have presented themselves to the eyes of a traveller during the Roman occupation on his arrival at the top of Hardknott Pass, 1,290ft. above the level of the sea. He pointed out the Roman parade-ground, now locally designated the bowling-green, on account of its level surface, and described other features of the Roman camp. The camp, he said, covered between three and four acres. The south-western gateway was covered by a natural mound or traverse of rock, the gate itself being probably double. The north-west gate was a single gate, the total opening, 10ft., being only about half that of the other three gates. As it opened almost immediately upon a precipitous cliff, it was probably little used, except for the relief of sentries and for the barrack labourers to carry

out the camp refuse daily, which was pitched over the cliff, as they knew was done at the Roman camp at Maryport. A little search at the bottom would probably reveal the kitchen midden and refuse-heap of the garrison, and they hoped to find it next summer. The north tower stood on a rocky knoll, and occupied much the highest part of the camp. The towers consisted of a basement of stone, perhaps used as storehouses; the upper portions were probably of wood. The north-east gate was a double gate, and was 19ft. 7in. in the opening. He described the buildings within the camp—the forum, which had been cleared out sufficiently for the whole plan of it to be recovered; the eastern group of building, comprising the barracks; the western group, which probably contained a stable with harness-room. They found no prætorium, or quarters for the commanding officer; but it was evident from the poverty of the relics that no officer of rank was here in command, probably no one above the rank of a centurion. A large area of the camp had no buildings; there might have been wooden huts to shelter troops marching through, or they might have encamped on the parade ground. The castle, with its walls, gates, and towers, must have been a picturesque feature in the scenery of Eskdale. The excavations which had been made in the camp had revealed pottery, bones, glass, lead, iron, bronze, flint, and charcoal, generally in fragments. Outside the camp, near the road, Mr. Calverley had unearthed a circular building of 15ft. internal diameter, still standing about 4ft. high, with a door approached by a ramp from the road. This building bears a striking resemblance to the famous building on the Carron, in Scotland, known as King Arthur's Oon, now destroyed, and, like it, would have a beehive roof of stone. The president thought that this had been a temple, and contained the image of some god or goddess patron of travellers. Close to this temple Mr. Calverley has found the ruins of a three-roomed house, with hypocausts, and also a bath. Behind the house a reservoir had been formed by damming up the stream. The president conjectured that this was a wayside tavern, for the refreshment of travellers.

CHIPS.

A new marble font was last week dedicated in the parish church of Lyndhurst. It has been executed by Mr. G. W. Seale, of Brixton, who has done nearly all the carving which enriches the interior of the church, the architect being Mr. J. L. Pearson, R.A. The cost of the font was £170.

An adjourned meeting of the Gateshead School Board was held on Friday to decide on certain matters in connection with the proposed Shipcote School. On the question of plans for the school, the Rector moved that the appointment of architect and the selection of plans be decided by open competition. To this an amendment was moved that Mr. Dunn, of Newcastle-on-Tyne, be appointed architect. Four voted for the amendment and four against. One member did not vote, and the chairman declined to give his casting vote, so the matter stands over.

A new Foresters' Hall, adjoining the Railway Hotel, at Woolston, Southampton, was opened on Wednesday week. The chief room measures 58ft. by 26ft., and adjoining are bar, committee-room, and lavatories. Mr. W. H. Chapman, of Woolston, was the builder.

At Great Salkeld parish church, near Penrith, a new Cambridge quarter clock, showing the time upon one external skeleton dial, painted and gilt, 4ft. 6in. diameter, with copper hands, painted and gilt and balanced within, has just been erected. The makers are Messrs. Potts and Sons, clock manufacturers, Guildford-street and Cookridge-street, Leeds, makers of the Penrith parish church clock; and chimes, and the Carlisle Corporation Markets large clock and bell.

The fourteenth annual festival octave, in commemoration of the reopening of Tewkesbury Abbey in 1879 (after restoration from Sir Gilbert Scott's designs), took place last week. This year's commemoration gains special significance from the fact of the abbey having of late received many most elaborate and costly gifts. An oak chancel screen has been erected by Archdeacon Robeson, and last week Messrs. Hardman and Co. completed the erection of five stained-glass windows, with Scriptural subjects, in the north aisle of the nave. The sculptured doorway leading from the nave into the cloisters, the restoration of which was undertaken by Mr. T. Collins during the year he was Mayor of Tewkesbury, has also just been completed, and several other stained-glass windows (not yet erected) have lately been promised to the abbey.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

SOCIETY OF ARCHITECTS.—The meetings of this Society for 1892-3 have now been fixed as follows:—Nov. 15th President's address, Nov. 29th, December 13th, January 10th and 24th, February 14th and 28th, March 14th and 28th, April 16th, May 16th, and June 20th annual meeting.

THE GLASGOW INSTITUTE OF MEASURERS.—The twelfth annual meeting of this institute was held in Glasgow on Monday, Mr. Robert Scott, president, in the chair. Reference was made to the Building Regulations Bill, which the council had considered in detail, and reported upon in a memorandum of suggested modifications. The scheme of professional examination, for which twenty-eight candidates had entered, was postponed till next year. The office-bearers for the ensuing year were elected as follows:—President, William Howatt, 146, Buchanan-street; vice-president, John H. Ramsay, 194, St. Vincent-street; secretary and treasurer, Colin Young, 113, West Regent-street; auditors of professional accounts, Messrs Robert Scott and John Muirhead. Other members of council are:—James Howatt, John Danskin, James D. Herbertson, Alexander Knox, John Morrison, Robert Reid, and John Currie.

LIVERPOOL ARCHITECTURAL SOCIETY.—The first meeting of the session took place at the Royal Institution on Monday evening last, when Mr. T. Harnett Harrison, F.R.I.B.A., gave his opening address, which took the form of a disquisition on climatic influence on art. He pointed out that art reached its greatest perfection amongst the nations inhabiting the Temperate zones, and advanced the theory that people who experienced hardships and difficulty in providing the necessities of life were too much occupied in attending to the "first law of nature" to care much for the merely beautiful. This is the first part of a paper to be finished at the last meeting of the session, when the author will, no doubt, point a practical lesson as the outcome of the original line of thought he has taken. The society is active in pushing forward education, and has arranged for students' classes, when lectures will be given on Thursday evenings during the months from October to March inclusive, on the following subjects:—"Stresses in Structures and Shoring," James Dod; "History of Architecture," H. W. Keefe; "Building Construction," David Lyon; "Specifications and Quantities," H. L. Beckwith, F.S.I.; "Mouldings, Features, and Ornaments," C. E. Deacon, F.R.I.B.A.; "Sanitation," T. Harnett Harrison, F.R.I.B.A. These lectures are free to all members of the society, and as a direct result of their formation, a considerable accession of new members has taken place.

MANCHESTER.—The first sessional meeting of the Manchester Society of Architects was held at the Literary and Philosophical Society's Rooms, George-street, in this city, on Tuesday evening, the president, Mr. Salomons, in the chair. Mr. F. W. Bedford, A.R.I.B.A., read a paper on "Some Account of the Arts in Sicily," which was illustrated by lantern views and sketches. He lightly touched upon the remains of Greek temples of the Dorian colony, and chiefly devoted his remarks to the Christian architecture. Illustrations were given of the interiors, showing, besides the varied marbles and sculptured work, the beautiful mosaics covering the walls and in some cases the ceilings of the churches and cathedrals, amongst the number being those at Palermo, Monreale, Cefalu, &c. The lecturer pointed out that it was only through these buildings that we could judge whether polychromy by opaque pictures in mosaic or by translucent pictures in the glass of our stained windows is the more beautiful mode of decorating an interior. A very large and admirable collection was exhibited of drawings made during a year's tour in Italy by the lecturer as Owen Jones Travelling Student of the Institute. A hearty vote of thanks was accorded to Mr. Bedford for his excellent and valuable paper.

The London County Council resolved on Tuesday to take the necessary steps for the purchase of the North Metropolitan Tramways. Amendments calculated to delay a decision, and to provide that the Council should not work the line if it was purchased, were negatived, and the original proposal was carried by 92 votes against 24.

Building Intelligence.

BRADFORD.—A new church, to be dedicated to St. Clement, is being built at the junction of Gilpin-street and Barker-end-road, Bradford, as a family memorial of the late Viscountess Mountgarret. It will be Perpendicular in style, and will seat between 600 and 700 persons. The nave will be 88ft. by 23ft., exclusive of north and south aisles, and 12ft. in width, and covered by an open-timbered roof. The chancel will be 62ft. in length, and adjoining it will be vestries and an organ-chamber. The external work will be of rubble from Idle, and the interior walling of red Cumberland sandstone. The flèche of oak will rise to a total height of 98ft. The internal paving is of wood blocks. Mr. E. Prioleau Warren, of Westminster, is the architect, Mr. Sutton the clerk of works, and Messrs. Wheeler Brothers, of Reading, are the contractors. The outlay will be about £12,000.

CAMBERLEY.—The memorial stone of the new church of St. George at Camberley, Surrey, was laid on Michaelmas Day. The site is at the termination of Obelisk-road, leading to the Knoll-road. The style adopted is Early English. The nave will be 68ft. by 26ft. The chancel will be 32ft. by 23ft. There will be a vestry and organ-chamber, 15ft. 6in. by 11ft. 6in., on the north side of the chancel; a clergy vestry will be added at a future date. The height of the nave, under the ridge, will be 47ft. 6in., and to the wall-plate 23ft. The narthex at the west end, in which is the principal entrance and a baptistery, opens into the nave by triple arches. The material will be brick, with dressings of Ham Hill stone. The church is to be lighted by single and double lancet windows and a five-light window in the chancel. The wood flèche to contain the bell is 31ft. above the ridge. The paving is to be wood-block throughout. The architect of St. George's is Mr. Arnold Hoole, and the builders are Messrs. Norris and Sons, of Sunningdale.

FOLKESTONE.—On Sunday last services were for the first time held in the new school-chapel, which has been built at The Grange, Folkestone. The walls are of red local brick throughout, with corbels, copings, and crosses of Morley red-stone. The seats, which are in oak, face east and west—the apse of the chapel facing north—and are arranged to accommodate 72 boys, 6 masters, and 32 visitors. The roofs are of pitch-pine, and are covered with local tiles. The architect is Mr. Arthur Blomfield Jackson, of London, under whose direction the work has been carried out by Mr. H. R. Mercer, of Folkestone.

IPSWICH.—The new premises of the Young Men's Christian Association in Tavern-street were opened on Thursday in last week. The old Bank House in the main thoroughfare of the town has been purchased for £3,600, and has been altered and added to at a further cost of £1,450. The chief room on the first floor is 48ft. by 19ft., and is seated for 200 persons. The frieze is decorated with a free design, representing flying storks, designed and executed by Mr. Bertram Binyon, a nephew of the architect. Other rooms include reading-room, committee rooms, and a suite of ladies' rooms. The old garden at the rear of the premises has been left, and will be used as a lawn-tennis court. Adjoining is a new gymnasium of red brick, 52ft. by 28ft. The alterations have been carried out by Mr. F. Bennett, from the plans of Mr. Brightwen Binyon, F.R.I.B.A., of Ipswich, the honorary architect.

KIRKCALDY.—The new public park at Kirkcaldy was opened on Saturday week. The area is about 108 acres. There are some handsome entrance gates, and the lodge is a highly ornamental one. A noble-looking bandstand occupies a prominent position on the rising ground a little above the lake, and has been erected by Messrs. Steven Bros. and Co., of 4, Upper Thames-street, E.C. It is constructed of cast iron on a raised stone base, and is of very ornamental design. It is octagonal in shape, surmounted by a dome of high pitch resting on eight columns with floriated capitals, and having ornamental brackets supporting the beams, which are of very elaborate scroll-work. Each bay in the octagon is filled in with a very handsome scroll-work railing, in the centre of which is the Kirkcaldy coat-of-arms. The various points are finely brought out by the free application of gold and colours, the town's arms being of gold on a blue

shield surmounted by the motto "Vigilando Munio," also in gold.

NEWCASTLE-ON-TYNE.—The foundation-stone of the Rutherford College was laid in Bath-lane on Wednesday. The building will have a frontage of 120ft., and will consist of basement, ground floor, and first, second, and third floors. In the basement will be dining-rooms for boys and girls, metallurgical laboratory, &c. On the ground floor is the large examination and assembly hall, 63ft. by 40ft. This will have a gallery and a platform. There are also, on the same floor, a physics lecture room, 42ft. by 26ft.; a second physics lecture room, 40ft. by 20ft.; a physics laboratory, 61ft. by 20ft.; a preparation room, 20ft. by 16ft. 9in.; a small optical room, master's room, lavatory and cloak room, &c. On the other side of the corridor, there are a committee room and registrar's room on one side of the lobby, and, on the other side, a library and reading room, 51ft. 10in. by 20ft. The assembly hall and physics lecture room run up through the first floor, the gallery being on a level with the first floor. There are, besides, on the first floor, six classrooms. On the second floor, the central space is occupied by the lights of the assembly hall. On three sides of this are the following rooms:—Still life room, antique room, master's room, general cast room, model drawing room, and an elementary art room. On the other side of the corridor are:—Modelling room, building construction room, and machine construction room. On the third floor are the following:—Chemistry lecture preparation room, chemistry lecture theatre, two small dispensaries, teacher's room, elementary chemistry laboratory, balance room, honours chemical laboratory, organic combustion room, biology preparation room, physiology preparation room, and a physiology and biology laboratory. The tower will be used as an astronomical laboratory. Messrs. Oliver and Leeson, of Morley-street, Newcastle, are the architects. The whole contract for the building has been given to Mr. Alexander Pringle, of Cramer Dykes, Gateshead. The ventilation will be on the Plenum system, the air being forced into the building instead of extracted. The air is warmed, and, if deemed well, disinfected at the basement, and forced by means of engine and fan into the different parts of the building. It is proposed to supply 1,500ft. of cubic air per hour, warmed to the requisite temperature, and filtered through a watered screen to each student. The cost of the college will be £15,000.

PRESTON.—The ceremony of laying the foundation-stone of the North and East Lancashire Deaf and Dumb Schools, Preston, an institution which owes its existence to Miss Cross, of that town, was performed on Saturday by the Earl of Lathom, with full Masonic ceremonial. The site is in the Blackburn-road. The building will provide accommodation for fifty children, but the plans are so arranged that, should the necessity arise, the accommodation can be doubled at comparatively small cost. There is provided on the western side a boys' wing, with a large day-room 23ft. 6in. by 18ft., teachers' rooms being placed at either end. In the event of extension these latter will be removed, and the length of the room will then be 36ft. A wing for the girls is placed at the east side of the buildings; the accommodation provided is not so great as that for the boys. The governor's residence is placed in the centre of the buildings, and there is also a board-room, together with a sick ward and a block where the administrative work of the schools will be carried on. The plans have been prepared by Messrs. James and Green, architects, of Blackburn, and the cost of the present section of the work is estimated at £5,200.

SALFORD.—The foundation-stone of a technical school for the borough was laid on Saturday. Mr. Henry Lord, of Manchester, formerly a member of the Salford Town Council, prepared the designs for the school. Messrs. Wilson and Toft, builders, City-road, are the contractors for the foundations. The building is set back a short distance from the street, and its main front stretches northward into Peel Park for more than 300ft. It is to be of red brick and terracotta, and will be from 80 to 90ft. in height. Provision will be made for the teaching of physics, mechanics, engineering and the handicrafts associated with it, joinery, turnery, wood-working, plumbing, building construction, drawing, modelling, painting, spinning, weaving, dyeing, cookery, and some of the minor in-

A new edifice is being built for the accommodation of the treasures of the National Library of Florence. The new structure will be lighted by electricity, and will employ the telephone, elevators, and all modern aids to quick communication and delivery. It will have nearly four miles of shelves in a separate stack-room, in eight stories, averaging about 12ft. high. An ultimate capacity of 2,000,000 volumes is contemplated. The reading-room is about 40ft. by 70ft., with the desks and seats in amphitheatrical arrangement. The grand staircase will be adorned with a portrait fresco, "The School of Florence."

Legal.

CONTRIBUTORY NEGLIGENCE.

QUESTIONS of contributory negligence are especially common in cases of accidents of the kind that happen about buildings and the like. They constantly crop up in cases of Employers' Liability and in other similar claims. But contributory negligence on the part of the plaintiff will only be a good defence if it can be shown that but for his own negligence the accident would not have happened to the plaintiff. Indeed, it has been held that the defence of contributory negligence is of no avail unless the defendant can show that the plaintiff's negligent conduct was the proximate cause of the accident. There may easily be some negligence on the part of the plaintiff, which will not in any way affect his right to recover, and this, too, even although it may have indirectly aided in bringing about the accident, so long as it was not the active and proximate cause. In these cases much must depend upon circumstances, and subject to this general rule each action will stand on its own merits. Many defendants are apt to be over-hasty in thinking they have evidence of the plaintiff's contributory negligence, when all they can produce is something said at the time of the occurrence by the party injured, and who was in complete ignorance of the way in which the accident had happened.

A good instance of this can be found in the recent case of "*Bythesea v. Palace and Burlington Hotels Co., Ltd.*" (*Times*, 21st July). In this case the plaintiff sued for damages for injuries caused by the negligent management of a passenger lift at the hotel, and she recovered a verdict for £75. The defendant company now moved for a new trial on the ground that there was a clear case of contributory negligence, as admitted by the plaintiff herself at the time. From the fact it appeared that the occurrence took place on a Sunday evening at the Buckingham Palace Hotel, when the passenger lift was being worked by a relief man, who was not used to it. The lift was a small one, with only sitting-room for two. The plaintiff, with two other ladies, got in to go up to their rooms. The man in charge opened the valve, but finding there was not pressure enough for the load, he opened the door and asked one of the ladies to alight, forgetting to turn off the valve. The lady standing up got out, and the plaintiff was going to follow her, when the lift-cage, thus lightened, and the valve being open, it ascended, and threw her forward to the ground, causing injury. She said at the time to the man and others that it was entirely her own fault; but when it was afterwards explained to her how the thing worked, and that the accident had been caused by leaving the valve open, she brought this action. The Court of Appeal now held that there was no evidence of contributory negligence, for the plaintiff had spoken of its being her own fault in entire ignorance of the cause of the accident, which was clearly the man's negligence as to the valve.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

LEGAL INTELLIGENCE.

WHAT IS A WAREHOUSE UNDER THE BUILDING ACT?—Messrs. Holland and Hannen, of Duke-street, Bloomsbury, were summoned before Mr. Vaughan, at Bow-street on Tuesday, by Mr. Frederick Wallen, the West St. Pancras district surveyor, for infringing section 27, sub-section 4, of the Metropolitan Building Act by erecting an additional building on the site of 40 to 43, Grafton-street, containing more than 216,000 cubic feet of air, and omitting to divide it by party-walls in such manner that the contents of each division should not exceed that number of cubic feet. It was explained for the prosecution that the premises were being built as an extension of those of Messrs. Shoobred, and constituted an infringement of the Act, not being a warehouse. He contended that a fireproof floor, by which the building was divided, was not to be constructed as a division like a party-wall. The lower part of the building would be employed in retail trade, and that above the fireproof floor as a dining-room and kitchen for the persons employed. Mr. Frederick Wallen said the building was approaching completion, and was

covered in. The top floor was a lavatory and scullery, and the second a kitchen. Then came a fireproof floor, below which were dining-rooms. The floor was made of iron beams and concrete, composed of coke breeze and Portland cement, and was 7in. thick. Over this was a tiled pavement 1½in. thick, and below a plaster ceiling. The remaining floors were ordinary floors of the same thickness. There were four openings in the fireproof floor, which appeared to be meant for lifts. The building consisted of six stories, in addition to a basement, giving a total height of about 88ft. The cubical contents of the whole building, without the staircase, were 272,800 cubic feet, the staircase representing 16,656 cubic feet more. The cubic contents of the part above the iron floor were 62,087 cubic feet. By Mr. Vaughan: The floor was not equal to a party-wall. A party-wall in this case should be 13in. thick, and, being built upright, gave support. In case of fire, the flames would act more strongly on a horizontal surface than on a perpendicular one. Mr. Grain, for the defence, contended that the building did not come under sub-section 4 of section 27, but came under the dwelling-house class, and that they were not bound to build party-walls. It was not in the warehouse class. It was admitted that it was being erected in conformity with the rules affecting dwelling-houses. There was no difference between it and a shop in which people lived over the place of business. Mr. Holland, architect, explained the construction and planning, stating that no floor contained 216,000 cubic feet of space. Mr. Ebenezer Gregg, Mr. F. A. Rooney, and Mr. Francis Chambers gave expert evidence as to the building being in the dwelling-house class. There was no limitation to cubic contents in that class. The Act defined all buildings as public buildings, warehouses, and dwelling-houses. This was neither a public building nor a warehouse, and must, therefore, be a dwelling-house. Mr. Dalby argued that this expert evidence was useless, as the sub-section spoke of any building used "wholly or in part for the purpose of trade and manufacture," and this was one. It was clear that a part of the house was used for the purpose of trade. The floor was not a party-wall. Mr. Vaughan: You can have a horizontal party-wall. Mr. Dalby thought not. The implication was that a wall was vertical.—Mr. Vaughan reserved his decision, and adjourned the summons for a fortnight.

IMPORTANT ARBITRATION AT EDINBURGH.—The proceedings in the arbitration between the Corporation of Edinburgh and the North British Railway Company in reference to the price to be paid for the land taken by the company from Princes'-street Gardens, were commenced on Monday in Dowell's Rooms, Edinburgh. Lord Shand is the overman; Mr. Dunlop, Westminster, the arbiter for the Corporation; and Mr. James Davidson, Saughton Mains, the arbiter for the railway company. The corporation claim payment of a sum of £150,000. In all probability the claim by the War Department will be dealt with at the close of the arbitration between the corporation and the railway company. The witnesses already heard include Mr. Cooper, borough engineer of Edinburgh; Mr. Vigors and Mr. Gerrard, land valuers, London; Mr. Dick Peddie and Mr. G. Washington Browne, architects, Edinburgh; Mr. McLaren, architect, Dundee; and Professor G. Baldwin Brown, Edinburgh University, who were all called on behalf of the corporation.

BUILDERS' LIABILITY FOR ACCIDENTS.—On the 3rd inst. a singular building dispute was heard before Judge Lumley-Smith and a jury at the Bow County Court, by which Frederick Challis, a builder's labourer, of Plaistow, sued Cornelius Mansfield, builder and town councillor, of Forest-lane, Stratford, to recover £50 for injuries sustained through the alleged negligence of defendant. Plaintiff's case was that on April 29th he was engaged by and with defendant to pull down an eight-roomed house at Maryland Point, Stratford; that three walls remained to be pulled down on the second floor; that defendant himself and a man named Salmons were assisting, when defendant took an iron bar, probed the bricks out, and the wall fell inwards into the room, instead of outwards into the garden, and the beams at the top fell on to the joists on which they were standing, which broke, and they fell to the basement floor, a distance of 15ft. He was picked up partly insensible, was unable to work again for fifteen weeks, and was not able to work properly now. Three witnesses corroborated, each swearing positively that it was the falling of the beams which caused the joists to give way. Defendant's version was that the beams were removed before the wall was unpinning, as it would be only suicide to attempt to knock down the wall whilst the beams were standing. The defendant could not be guilty of negligence, as he fell himself, and was laid up for five weeks. Four witnesses also swore positively that the beams were taken away the previous day, and that it was the weight of the fallen wall which caused the joists to break. They had knocked

down eight walls, and each of the others fell outwardly. The jury returned a verdict for plaintiff, damages £35. His Honour certified for costs.

IN RE R. YATES, OF SHIFNAL.—At the Madeley County Court on the 21st ult., Richard Yates, builder and contractor, Shifnal, was publicly examined as a bankrupt. The statement of affairs shows gross liabilities amounting to £6,376, of which sum £2,253 18s. 11d. is due to unsecured creditors. There are creditors fully secured to the extent of £3,603 17s. 2d., and others partly secured to the sum of £500. The assets are estimated to produce £275 18s. 11d., including £386 15s. for stock-in-trade and trade fixtures, and £1,313 4s. 3d. book debts, the deficit being £533 7s. 4d. Bankrupt succeeded his father in business at Shifnal in 1871. The liabilities connected with the concern which he took over reached £4,407, and the assets £4,326. The examination was adjourned.

INSUFFICIENT THICKNESS OF WALLS.—On Sept. 27 at the Lambeth Police-court, before Mr. Biron, Q.C., Mr. W. J. Goldsworthy, builder, was summoned at the instance of Mr. Ellis Marsland, district surveyor for Camberwell, for erecting in the Friern-road, East Dulwich, a three-story building, exceeding 25ft. in height, with walls only 9in. in thickness. The surveyor produced a section and photograph of the building, showing that the height to the top of the topmost story was 28ft. 2in., and that according to Part I. of the First Schedule, Table 2, of the Building Act, the thickness of the ground story should be 13in. On the part of the defendant it was urged that the rooms in the roof were only box rooms, but as one was 7ft. 6in. in height, and the other 9ft. 2in., and each contained a window and one a fireplace, the magistrate was clearly of opinion that the two rooms constituted a story, and made an order that the top story should either be removed, or the walls on the ground story made 13in. in thickness.

IN RE I. CRANSTON, OF ALDERSHOT.—Under the failure of Irvin Cranston, builder, of Aldershot, it appears that the gross liabilities amount to £2,660 13s. 4d., of which £1,131 7s. 10d. is due to unsecured creditors, to fully secured creditors £1,418 18s. 9d., the value of the securities being estimated at £1,850, thus showing a surplus of £421 1s. 3d. The total net assets are £867 19s. 1d., disclosing a deficiency of £313 8s. 9d. The debtor alleges his failure to have been caused through losses on contracts. The debtor states that he commenced business as a builder and contractor about thirty years ago with a capital of £20. He was in partnership with a Mr. E. Smith about two years ago in connection with a brickfield at Aldershot. The debtor's books are imperfectly kept, and there is no cash-book. The debtor states he only became aware of his insolvency last July, when pressed by creditors.

RE H. TOTEN, SONS, AND YOUNG.—Under the failure of these debtors, builders, of Gloucester-road, South Kensington, and Maude-grove, Fulham-road, accounts have now been issued, showing liabilities £5,005, of which £4,534 is unsecured, and assets £1,101. The failure is attributed to losses through the carpenters' strike, the failure of a large debtor to the estate, to losses on other bad debts, and to losses by accommodation bills. The Official Receiver reports that the assets of the joint estate have been disposed of, with the consent of the principal creditors, for £1,000, and that a dividend will be declared as soon as possible.

BREACHES OF BY-LAWS.—At Exeter police-court, last week, Albert Hayman, a builder, of Exmouth, was summoned under three charges by the St. Thomas sanitary authority: (1) For not having, after the completion of the erection of a building at Withycombe, sent to the surveyor of the sanitary authority notice of completion; (2) for having covered up a drain in the said building, not having given notice to the surveyor of his intention to do so; and (3) for having constructed a cesspool not in accordance with the requirements of the by-laws. Mr. Harbottle, surveyor to the authority, said he had received no notice of the completion of the building, which was occupied, though not in a fit state to be occupied. The drains were not properly constructed, and the cesspit was covered over, and had no ventilation except into the house. Defendant said he had received no notice from the surveyor that anything was wrong. The chairman replied that defendant had a copy of the by-laws, and it was rather too much to expect a public body to instruct him in them. Defendant would be fined £1 for each offence and costs. There would be a further penalty of 40s. for every day on which the nuisances existed after defendant had received a notice to abate them.

WALSALL BUILDERS AND THE BY-LAWS.—At the Walsall Police-court on Friday, James Rowley, builder, Hope-street, was summoned for failing to provide a ventilation shaft for drainage on property in his occupation. Mr. Middleton (borough surveyor) proved the case, and defendant was fined 40s. and costs.—Alfred Westbury, Green-lane, was summoned as owner for non-provision of proper footings to a building in Green-lane. Mr. Middleton

said that in this case defendant had had a one-story shop erected, the walls of which had one course of footings only, instead of two. Apparently the offence had been committed by the builder employed. Defendant said that this was so; it was entirely the fault of the contractor. He promised to give a guarantee that no additional stories should be put to the building, and the case was adjourned *sine die*.

IN RE C. P. MILLS.—From the observations of the Official Receiver under a receiving order against Charles Phillips Mills, it appears that the debtor had for the past 13 years carried on business as a builder and decorator, up to 1881 in partnership with another person, but since then alone, at St. Mary's Works, Stoke Newington. He attributes his failure partly to a loss of £200 on leasehold house property, but also to depreciation in the value of freehold property at Page-green, Tottenham, and to interest on loans. The liabilities are returned in the statement of affairs at £1,375, of which £379 are unsecured, with assets £201. An adjudication of bankruptcy has been made.

CHIPS.

The Roman Catholic Cathedral of St. Andrew's, Great Clyde-street, Glasgow, which has recently undergone a thorough renovation, was reopened on Sunday. The chief alterations consist in the removal of the old side galleries, and the erection of two elaborately-carved altars of Caen stone, from designs by Messrs. Pugin and Pugin, Westminster.

The famous Tretyakov Gallery of pictures, by Russian artists, including a specially fine collection of Vereschagin's, has been bequeathed by the late owner to the city of Moscow, together with funds for the maintenance and extension of the gallery.

The Prison Commissioners are having extensive alterations carried out on the structure and arrangements of Greenock prison. A new entrance is being made to the governor's house, the prison courtyard is being improved, new offices constructed, and an additional story put on the tenement occupied as warders' houses. The cost will be about £1,800.

At St. Peter's Church, Hereford, the east window has been filled with stained glass as a memorial to the late vicar. The subject is the Ascension of our Lord, and the artists are Messrs. W. Pearce and Co., of Birmingham. The unveiling took place yesterday (Thursday) afternoon.

Sir George Reid, P.R.S.A., has presented to Aberdeen University a portrait of the Rev. Dr. Milligan, Professor of Biblical Criticism in the University. The portrait will be hung in the Senatus Room at King's College, Aberdeen.

The new Central Station, Wigan, constructed by the Manchester, Sheffield, and Lincolnshire Railway, was opened on Monday by Lord Cross, who said that it was hoped before long to carry the line on to the North.

A carpenter named George Bowden, in the employ of Messrs. Higgs and Hill, was at work on the Surrey County Buildings at Kingston, on Saturday, when he was killed by an accidental fall through a skylight opening in the roof. No one witnessed the accident, although there were fifty men at work on the building.

One of the first premiums awarded in the competition for the design of a new museum for Darmstadt has fallen to a Danish architect, Herr Neikelmann, who is established at Stuttgart. The other premium was given to Herren Schneiden and Speer, of Berlin. It is estimated that £75,000 will be required to carry out Herr Neikelmann's design.

Henry Aldridge, a warehouse clerk, has been remanded by the Birmingham stipendiary magistrate on a charge of arson. The prisoner was in the employment of a local firm of decorators and paper-hangers, John E. Lee and Co. Three fires, believed to be of incendiary origin, had taken place on their premises within the last fortnight.

The London County Council received, on Tuesday, a report as to the progress that is being made with the Boundary-street scheme under the Artisans' Dwellings Acts. Of the 183 claims, 159 have been settled for £228,317, the amount claimed having been £385,656. Notices have been served for closing 135 houses, and 121 more are to be closed as soon as practicable, leaving 50 houses to be occupied and maintained in repair for the present.

South Morningside School, Edinburgh, which has just been completed by the St. Cuthbert and Dean School Board, was opened on Monday by Professor Masson. The school provides accommodation for 600 pupils, and the building can be added to without interfering with the work of the school when that is required. In addition to the ordinary classrooms, there are special rooms for cookery and sewing. The architect is Mr. R. Wilson, Queen-street, Edinburgh.

WATER SUPPLY AND SANITARY MATTERS.

INSANITARY DWELLINGS IN OLDHAM.—"An exceedingly bad state of affairs," to quote from the engineer's report on the case, was revealed last week by an investigation made into the state of property in a court off John-street, Oldham, by Messrs. Theodore S. MacCallum and E. Codling, civil engineers, of Manchester, by order of the borough coroner for Oldham. The property is of the back-to-back class. The fireplace on the upper floor was found to be bricked up air-tight, the drains were neither disconnected nor trapped, and were in addition so leaky that the sub-soil resembled a cesspool. It is to be feared that much property of this back-to-back class is in a similar insanitary condition.

LONDON WATER SUPPLY.—The Royal Commission on the water supply of London resumed its sittings on Wednesday, Lord Balfour of Bursleigh presiding. Mr. Thomas Hawkesley, past-president of the Institute of Civil Engineers, advocated a periodical inspection, in order to prevent waste, and recommended the formation of storage reservoirs in the lower parts of the Thames Valley. Rivers, he said, had great self-purifying powers. The water supply had never occasioned a cholera epidemic in the Metropolis. It was a remarkable fact the cholera always moved up rivers, and did not come down them. Mr. Peregrine Birch said a great deal more water might be taken from the Thames without injury to the river. Sir Frederick Bramwell, C.E., expressed the opinion that the consumption of water per head per diem in the Metropolis was made to appear much larger than it really was, owing to waste consequent to a great extent on leakage.

The restoration of the Grand Reception-room at Windsor Castle, which contains the famous "Golden Fleeces" tapestries, is nearly completed. The cream colour of the panelling has been retained, and the old gilding revived, and the apartment, which is one of the finest among the State Rooms, now presents a very handsome appearance. The work is carried out under the supervision of Mr. Collmann, her Majesty's Inspector of the Palace.

Among purchases recently made for the National Portrait Gallery are a study in full length of Lord Nelson, drawn in 1802 by Henry Edridge; a likeness of Thomas Girtin, by John Opie; Viscount Castlereagh, by Sir Thomas Lawrence; Thomas Killigrew, by Vandyck; John Leech, by Sir John Millais; an equestrian sketch in oils of Marlborough, by Sir Godfrey Kneller; and the Earl of Lincoln, by Ketel.

The city council of Bristol have under consideration a scheme recommended by a committee for creating a Greater Bristol. The districts proposed to be included embrace St. George, Kingswood, Stapleton, Horfield, Westbury, a portion of Henbury, Shirehampton, and the out-parish of Bedminster. The acreage of the borough would thus be increased from 4,971 to 23,000 acres, the total population according to the last census would be about 272,000, and the rateable value would be raised from a million to a million and a quarter.

The parish church of Minshall, which has recently been undergoing renovation, was reopened on Tuesday week by the Bishop of Chester. The church was built in 1772, and had become dilapidated. To Mr. Matthews, builder, of Nantwich, was intrusted the work of renovating the exterior, which mainly consisted of the putting on of a new roof, the building of new stone pinnacles to the tower, and the pointing of the walls. The interior of the church has been decorated by Mr. Davies, of Nantwich; and the chancel has been inlaid with mosaic work. The cost has been over £500.

Birmingham is emulating the example of Manchester by decorating its town hall with paintings illustrative of the history of Birmingham. The corporation are, says a local journal, setting about the undertaking in an original way. No competition is announced, and no Royal Academician has been approached; but the cartoons are being produced in the School of Art by students under the superintendence of the head master, Mr. Taylor. The first design, by M. Gehr, is already completed, and ready to be transferred to its appointed place.

The Lord Mayor opened the Camberwell Public Baths and Washhouses in Church-street on Saturday afternoon. In the building, which has cost £28,575, are 64 private baths for men and 32 for women, together with first and second-class swimming-baths for men, both of equal dimensions—viz., 120ft. by 35ft. Each of these latter contains 130,000 gallons of water, and can be completely emptied in an hour. There is also a public laundry, which contains 69 washing compartments. Messrs. Spalding and Cross, whose design was selected in competition three years since, were the architects. The zinc roofing has been executed by Messrs. Holden and Co., of 5, Wood-street, S.W., on their patent unsoldered system.

Our Office Table.

THE design and appearance of the present silver medal given by the Architectural Association being considered by some members of the committee unsatisfactory, Mr. Leonard Stokes, past president, mentioned the matter to Mr. Alfred Gilbert, A.R.A., who generously offered to design a new medal, not as an ordinary commission, but as a personal gift to the association. A model in wax of Mr. Gilbert's design will be on view either at to-night's conversation at the Imperial Institute, or at the annual meeting at 9, Conduit-street a fortnight later.

WE have to announce that two courses of lectures will be given on Applied Art by Mr. Hugh Stannus, F.R.I.B.A., in the University of London. Each course will consist of ten lectures, on Tuesdays and Thursdays from 7 to 8.30 p.m. The first course will illustrate the application of ornament in architectural decoration, and will extend from Tuesday, 11th of October, to Thursday, 10th of November next, both inclusive. The second course will treat of vase-form and vase-decoration, and will extend from Tuesday, 15th November, to Thursday, 15th of December. The lectures will be illustrated by diagrams, drawings, and photographs, and the fee for both courses is £1 1s. To all students of architecture and ornamental art, these lectures by so competent an authority cannot fail to be instructive.

THE twelfth annual meeting of the members of the Birmingham Guild of Handicrafts was held on Monday night at the workshop, Lower Priory, under the presidency of Councillor A. Dixon. The annual report showed that, owing to the demolition of the workshop in Lawrence-street, and the necessity of carrying on their work in temporary premises during the building of the new workshop in Sheep-street, the guild had been working under some disadvantage during the past year. In spite of that, however, the membership of various classes had been well maintained, and good progress had been made in their work. The Treasurer reported that there had been a large increase in the sale of work. Arrangements had been made with the University of Oxford for the formation in connection with the guild of a course of university extension lectures for working men. The recreative classes for the winter season reopened on Tuesday evening. They include drawing, chip-carving, carpentering, wood-carving, leather-work, and metal work.

AN account of the practices of the building trade guilds, which still exist in the remoter provinces of Austria, and keep up customs which have descended from the Middle Ages, is given by Herr Franz Paul Piger, of Iglau, in the *Bautechnische Zeitschrift* of Berlin. In the case of Austria, these traditional practices have a peculiar political interest, inasmuch as it is by means of the trade guilds that German national feeling, and the German language itself, has been kept alive in districts where the German inhabitants would have been absorbed in the flood of Slavonic immigration had it not been for these trade corporations. Although the trade guilds have now no official standing, and a great deal of building is executed without their aid, they maintain their organisation and many of their old customs; and their members, proud of their position, look down with contempt upon the "day-work men," whom they regard as ignorant interlopers. The principal building corporations are those of the masons and carpenters, who have never yet been able to settle the question, which has harassed them since the Middle Ages, of the comparative dignity of the two corporations. At present, the rules of the masons' and carpenters' guilds are nearly the same, and in each, admission to membership is only to be had after three years of apprenticeship.

MR. PERCEVAL, the Agent-General for New Zealand in London, forwards a report of the Bureau of Industries explanatory of the new system of constructing roads and railways by what are called co-operative contracts. In these a small party of men, generally six in number, is allotted a certain section or length of road or line; one of them is elected a "ganger" and trustee for the others, to deal for them with the Government. The Government engineer states a price for the portion of work, and, as this is done by an unprejudiced officer, it is generally accepted without murmur by the men. The

results usually have been very satisfactory. Progress payments are made fortnightly, for the benefit of the men's families, and the whole amount is paid up in cash on the work being passed by the engineer. It is the intention of the Government to provide small farms of 10 or 15 acres each for these workmen, in village settlements, so that they may be induced to make their homes in country districts, and thus in some degree to neutralise the centralising tendency of modern industrial life.

The Architectural Association, 9, Conduit Street, W.; and 56, Great Marlborough Street, W.

THE ARCHITECTURAL ASSOCIATION COURSES OF LECTURES, CLASSES, and STUDIO INSTRUCTION WILL COMMENCE ON MONDAY, October 10.

The Courses are both Elementary and Advanced, and are designed to provide a sound professional education, supplementary to that to be obtained by the prevailing system of pupils. The Course, which is in four divisions, is progressive and consecutive, and the instruction is given by Lecturers and Instructors of known ability.

DIVISION I.

LECTURES AND CLASSES.—The Orders of Greek and Roman Architecture, Building Materials, Perspective, Physics.

THE STUDIO.—Drawing from Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Plane Geometry, Criticism Meetings.

DIVISION II.

LECTURES AND CLASSES.—English Architecture, Materials, Elementary Ornament and Colour Decoration, Strength of Materials, Stresses and Strains.

THE STUDIO.—Designs based upon Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Solid Geometry, Criticism Meetings.

DIVISION III.

LECTURES AND CLASSES.—The History of Architecture, Materials, Colour Decoration, Sanitary Science as applied to Drainage and Water Supply.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Perspective and Sciography, Constructive Masonry, Criticism Meetings.

DIVISION IV.

LECTURES AND CLASSES.—The History of Architecture; Sanitary Science—including Ventilation, Lighting and Heating, Painting, Sculpture; other Arts allied to Architecture; Professional Practice—including Legislative Enactments relating to Building Contracts.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Drawings of Ancient Buildings from actual measurement, Graphic Statics and Perspective, Criticism Meetings.

EXTRA SUBJECTS.

LECTURES AND CLASSES.—Plane and Solid Geometry, Geology, Mensuration, Land Surveying and Levelling, Chemistry of Building Materials, Quantity Surveying—including the Preparation of Estimates, Discussion Section.

THE STUDIO.—Sketching and Measuring, Elementary Water Colour Class, Water Colour Class, Modelling.

A Pamphlet, containing full particulars of the curriculum, may be obtained free on application to the Hon. Secs. at 56, Great Marlborough-street, London, W. Fees must be paid in advance, and passes may be obtained at the Offices of the Association, between Ten a.m. and Seven p.m.

ERNEST S. GALE, } Hon. Secs.
F. T. W. GOLDSMITH, }

UNIVERSITY COLLEGE, LONDON.

Professor T. ROGER SMITH'S LECTURES ON ARCHITECTURE, CONSTRUCTION, and MODERN PRACTICE will be resumed in the week beginning October 9th.

The Evening Classes for the Study of BUILDING CONSTRUCTION and for STRUCTURAL DRAWING and ARCHITECTURAL DRAWING, established at University College by the Carpenters' Company, will be resumed at the same time. These classes meet from 7 to 9 p.m., and the fees are extremely moderate.

For further particulars consult the syllabus, to be obtained at University College, Gower-street, W.C.; and at Carpenters' Hall, London Wall, E.C.

J. M. HORSBURGH, M.A., Secretary.

The recently completed technical schools and free library for Ashton-under-Lyne were opened to students on Monday. The total cost of the buildings has been £16,000. Messrs. John Eaton and Sons, of Ashton, are the architects.

At a meeting of the town council of Edinburgh held on Tuesday a proposal that the burghs of Edinburgh, Leith, and Portobello should be merged into one municipality was approved generally, and it was remitted to the Lord Provost's committee to take the whole matter into further consideration and to report.

The election to the Disney Professorship of Archaeology will take place on December 1, at Christ's College, Cambridge. The professor is required to deliver six lectures at least in the course of each academical year. The professorship is tenable for five years, and the professor may be re-elected; but the present professor, Canon G. F. Browne, does not seek re-election.

A new Cottage Hospital has been erected at Warminster, and special attention has been paid to the ventilation, which has been carried out on the Boyle system, the latest improved form of the self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

M. Vital Gabriel Dubray, the Parisian sculptor, died on Tuesday, at the age of 74. He studied under the younger Ramey, was engaged on the Jeanne d'Arc memorial at Orleans, and executed statues of Napoleon, Sully, Lannes, and other celebrities.

The portrait of Sir Henry Macandrew, ex-Provost of Inverness, painted by Sir George Reid, P.R.S.A., was presented to the corporation of Inverness by the subscribers on Friday. It will be hung in the town hall of that city.

STATUES, MEMORIALS, &c.

EDINBURGH.—Designs for a memorial to the late Lord Justice-General Inglis, to be erected within the walls of St. Giles's Cathedral, have just been sanctioned. The memorial, designed by Dr. Rowand Anderson, architect, takes the form of a marble tablet with 17th-century features. Like the Montrose memorial, recently erected from the same architect's designs, the memorial to the Lord Justice-General will be executed in varied coloured marbles and alabasters. It will be placed on the east wall of the Preston aisle. The principal feature of the memorial is a central panel, the background of which will be a slab of Emperor's red marble. On this is superimposed a piece of drapery in white alabaster, looped up at the middle and at the sides, and on which is carved the following inscription:—"In memory of the Right Hon. John Inglis, of Glen-corse, Lord Justice-General of Scotland, Lord President of the Court of Session. Born August 21st, 1810; died August 20th, 1891." On each side of the panels are shields on ornamental backgrounds, one bearing the arms of the University of Edinburgh, and the other those of the University of Glasgow. In the centre of the pedestal panel are two figures supporting a shield bearing the heraldic insignia of the College of Justice, and in small panels, immediately under the base of the columns, are shields with the arms of the Universities of St. Andrew's and Aberdeen. The crowning feature of the tablet is a shield within a circle, carrying the personal arms of the deceased, and surmounted by the family crest—a lion rampant. The height of the monument will be 9ft., and its width 7ft.

CHIPS.

The chairman of the Oldham School Board opened last week the new extensions of the Westwood board schools. The works have been carried out by the executors of the late E. Whittaker, of Rochdale-road, Oldham, from plans by Messrs. Winder and Taylor, Union-street, Oldham.

The Bishop of London unveiled the memorial window to Mr. W. H. Smith in the church of St. Martin's-in-the-Fields yesterday (Thursday) afternoon at four o'clock.

A new hotel is about to be built at Llangamarch Wells, Radnorshire, at a cost of £20,000. It will contain about 700 beds, and the usual general accommodation. Mr. T. P. Martin, of Swansea, is the architect.

New carved oak choir-stalls, executed by Mr. J. Sharp, of Westbourne, and a wrought-iron screen and gate to chancel, were erected on St. Michael's Day in St. Michael's Church, Bournemouth, from designs by Mr. Reginald G. Pinder, F.R.I.B.A.

The Oldham town council have passed a resolution empowering the town clerk to apply to the Local Government Board for sanction to borrow £200,000, to cover the cost of constructing sewage works.

Extensive works of sewerage are being carried out for the Royton local board. The scheme of sewerage was originally designed by the late Mr. R. Vawser, C.E., and is being carried out under the direction of Mr. Theodore S. McCallum, of Manchester.

The new infirmary buildings at Aberdeen were opened by Princess Louise on Tuesday. The present is the sixth reconstruction of the buildings on the existing site since the foundation in 1739. The architect for the present work was Mr. Kelly.

M. Emile Signol, the painter, died on Wednesday, aged 88. He studied under Gros, and a number of his pictures are at Versailles and in Paris churches. He entered the Academy of Fine Arts in 1860.

A public inquiry relative to an application of the town council of Rochdale for sanction to borrow £77,000 will be opened to-day (Friday) by Mr. Arnold Taylor, engineering inspector of the Local Government Board. The £77,000 is made up of two items—£65,000 for gasworks purposes, and £12,000 for purposes of street widening and improvement.

In the case of the application for discharge from bankruptcy, made on behalf of John Edwards and David Edwards, trading as Edwards Brothers, of Treherbert, builders, the order of discharge has been suspended for six months, ending December 16, 1892. In the case of George Egbert Thomas, surviving partner of the late firm of Charles Thomas and Sons, of West Cowes, I.W., the discharge has been suspended for twelve months, ending May 4, 1893.

Mr. Edward Tidman, C.E., F.S.I., M.S.A., of Westminster, has just been appointed lecturer on Hygiene, and commences a course of lectures on Oct. 13 at Cheshunt, Herts, for the Cheshunt Technical Education Committee. Mr. Tidman is also lecturer for Essex on the same subject.

Trade News.

WAGES MOVEMENTS.

LONDON DISTRICT CODE OF WORKING RULES.—The United Trade Committee of Carpenters and Joiners have forwarded a circular to all builders in the Metropolitan district, drawing attention to the code of working rules for carpenters and joiners in the London district, agreed to and signed by representatives of the Central Association of Master Builders, and a representative of that trade (together with representatives of other trades), at conference convened for that purpose on June 10th and 23rd, 1892. They remind employers that the new code, the leading points in which are now well-known to our readers, will come into operation throughout the twelve miles radius from Charing Cross on and after the 7th day of November next.

LONDON BUILDING TRADES FEDERATION.—In spite of a downpour of rain, some four or five thousand of those engaged in various departments of the building trades took part on Sunday in a march to, and demonstration in, Hyde Park, the object of which was to celebrate the federation of the trades, and to discuss the steps to be adopted in view of the new arrangements which, as a result of lengthy conferences between those interested, come into force on the 7th of November. Four waggons had been set apart as "platforms," the respective chairmen being Messrs. D. Hennessey, Jeffrey, W. Baines, and L. Hall. A resolution was adopted pledging the federation to stand by the new rules, and to give both moral and financial support to any of the federated trades which might not participate in the advanced wages and shorter hours which are features of the new arrangements.

NELSON, LANCS.—The strike of plumbers at Nelson, Lancashire, has been settled on the men's terms, and work was resumed on Monday, the employers having agreed to transfer the plumbing apprentices objected to to the operative painters' department of their workshops.

Holloway's Ointment.—This cooling Ointment perseveringly rubbed upon the skin, is the most reliable remedy for overcoming all diseases of the throat and chest. Quinsy, relaxed tonsils, sore throat, swollen glands, ordinary catarrh, and bronchitis may be arrested as soon as discovered, and every symptom banished by Holloway's simple and effective treatment.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—T. PETTITT and CO., Lithographers, 28, Fitch-street, Soho, London, W. Established 50 years.

DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLEDITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—**THE HAM HILL STONE COMPANY**
NORTON, STOKES-UNDER-HAM, SOMERSET.

London Agent:—
Mr. E. A. WILLIAMS, 16, Craven-street, Strand W.C.

CRAIGLEITH STONE.

UNEQUALLED for Staircases, Steps, and Landings, especially for Public Buildings with great wear. **VERY HARD, and NEVER WEARS SLIPPERY.**

SOLE AGENTS for England,
J. & A. CREW, Cumberland Market, London, N.W.

WM. OLIVER & SONS,
MAHOGANY, WAINSCOT, WALNUT,
TEAK, VENEER, and FANCYWOOD
MERCHANTS,

120, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

BATH.—For constructing a wall and railings at the west end of Lower Common in Park-lane, for the city council:—
Long and Sons (accepted) £219 5 0

BIGGLESWADE.—For alterations and additions and a new furnace chimney shaft at the Union Workhouse, Biggleswade. Mr. E. Twelvetrees, Sandy, architect:—
Willmott, Hitchin £119 0 0
Bedhouse, Stotfold 114 0 0
Coleman, Bedford 998 0 0
Ruffell, Biggleswade 975 0 0
French and Ellwood, Sandy* 967 0 0
* Accepted.

BRIXTON, S.W.—For erection of new theatre, for the Brixton Theatre Company, Limited. Messrs. Crewe and Sprague, Fitzalan House, Arundel-street, Strand, W.C., architects. Quantities by Messrs. Brunson and Henderson, 47, Pall Mall, S.W.:—

Veale, G., and Co.	£14,850	0	0
Jarvis and Sons	14,777	0	0
Newmans, Limited	13,900	0	0
Bush, A., and Sons	13,870	0	0
Barnard, Wells, and Co.	13,700	0	0
Allen and Sons	13,465	0	0
Collis and Sons	13,415	0	0
Young and Londale	12,977	0	0
Kirk and Randall	12,720	0	0

(Architects' estimate, £12,500.)

BRACKLEY.—For new choir stalls at St. Peter's Church, Wickham-road, Brackley, S.E. Mr. John Jas. Downes, 11, The Parade, Lewisham, High-road, S.E., architect:—
Dorey, J., and Co. £903 0 0
Hawes, G. 293 10 0
Lorden, W. H., and Son (accepted) 269 0 0

CHADWELL HEATH.—For the erection of a row of four cottages at Chadwell Heath, near Ilford, for the Great Eastern Railway Company:—
Rogers and Robson, Brentwood (accepted).

DEPTFORD.—For new closets and sanitary matters under the Public Health Act, at Normandy Wharf, Ravensbourne-street, Deptford, for Mr. Walter C. Mockford, Mr. John Jas. Downes, 11, The Parade, Lewisham, High-road, S.E., architect and surveyor:—
Wilson, A. £82 10 0

DEPTFORD.—For the erection of new closets, &c., under the Public Health Act, at 292, Lower-road, Deptford, for Messrs. Slazenger and Son. Mr. John Jas. Downes, 11, The Parade, Lewisham, High-road, S.E., architect and surveyor:—
Wilson, A. £99 15 0
Best, S. R. 94 5 6

DEVON.—For constructing new bay windows throughout the County Asylum, for the Devonshire County Council:—
Phillips, H. (accepted).

EAST FINCHLEY.—For repairs and painting to lodges and greenhouses at the Cemetery for the Islington Burial Board. Mr. F. H. Barfield, F.S.I., M.S.A., 55, Lancaster-road, Stroud Green, N., architect and surveyor:—
Torrington, N. C., jun. £250 0 0
Stevens Brothers 205 0 0
Marchant & Hirst, Highgate-road* 139 10 0
* Accepted.

EAST FINCHLEY.—For erection of a cottage lodge, &c., at Irish Corner, for the Islington Burial Board. Mr. F. H. Barfield, F.S.I., M.S.A., 55, Lancaster-road, Stroud Green, N., architect and surveyor:—

Marchant and Hirst	£359	0	0
Stevens Brothers	357	0	0
Plowman, C.	355	0	0
McFarlane Brothers	352	0	0
Wheeler and Co.	339	10	0
Cooper, H.	337	0	0

GREAT YARMOUTH.—For additions to Cobholm Island School, for the Great Yarmouth school board. Messrs. Bottle and Olley, architects. Quantities by the architects:—

Bray, F. W.	£128	0	0
Barnard, M.	415	17	6
Eastoe, R.	378	18	0
Beech, G. W.	374	0	0
Grimble, T.	374	0	0
Moore, J.	369	0	0
Cooper, I. S.	362	17	0
Leggett, J. (accepted)	352	0	0

GREAT YARMOUTH.—For additions to Runham Vauxhall School, for the Great Yarmouth school board. Messrs. Bottle and Olley, architects. Quantities by the architects:—

Eastoe, R.	£445	8	0
Bray, W.	444	0	0
Grimble, T.	418	0	0

Beech, G. W.	410	0	0
Moore, J.	405	0	0
Leggett, J.	399	0	0

HIGH WYCOMBE.—For alterations to business premises, for Mr. H. Harvey. Mr. Thos. Thurlow, High Wycombe, architect:—

Flint, H.	£315	0	0
Hunt, C. H.	294	0	0
Gibson, G. H.	288	0	0
Looseley, W. R.	275	14	0
Harris, J. T. (accepted)	264	0	0

HIGH WYCOMBE.—For the erection of bakehouse, business premises, residence, and villa attached, for Mr. Benjamin Channer. Mr. Thos. Thurlow, High Wycombe, architect:—

Looseley, W. R. (accepted)	£1,949	0	0
Baker's oven:—			
Kirkby, J. (accepted)	110	0	0

HIGH WYCOMBE.—For erection of new chair manufacturing premises at High Wycombe, for Messrs. J. Cox and Son. Mr. Thos. Thurlow, High Wycombe, architect:—

Hunt, C. H.	£2,640	0	0
Flint, H.	2,277	0	0
Looseley W. R., Son, and Pearce	2,023	0	0
Harris, H.	1,936	0	0
Nash and Sons	1,925	10	0
Gibson, G. H. (accepted)	1,904	0	0

HIGH WYCOMBE.—For the re-erection of the Corporation Arms, for Messrs. Wheeler and Co., Wycombe Brewery. Mr. Thos. Thurlow, High Wycombe, architect:—

Hunt, C. H. (accepted)	£1,293	15	0
-------------------------------	--------	----	---

ISLINGTON.—For alterations to restaurant, confectioners' shop, bakehouse, &c., for Messrs. Galloway and Son, 230, Upper-street, Islington. Mr. Ernest H. Abbott, 6, Warwick-court, High Holborn, W.C., architect. Quantities by Mr. A. Johnson, 5, Imperial Buildings, Ludgate-circus, E.C.:—

Godden	£2,952	0	0
Shurmer	2,736	0	0
Wontner, Smith, and Son	2,634	0	0
Bywaters	2,580	0	0
Drew and Cadman	2,455	0	0
Hall, Beddall, and Co.	2,430	0	0
Anley, J.	2,372	0	0

LICHFIELD.—For building a new dining-hall, kitchen, laundry, and other works to the workhouse, Lichfield. Mr. W. H. Woodroffe, A.R.I.B.A., architect:—

Harley, J., and Son, Smethwick	£3,525	0	0
Hodges, G., Burton-on-Trent	3,590	0	0
Whitmore, A. F., Stafford	3,498	0	0
Parnell, J., and Son, Rugby	3,478	0	0
Varlow, J., Burton-on-Trent	3,472	0	0
Lowe, T., & Son, Burton-on-Trent*	3,287	0	0
Walkerline, W., Derby+	2,860	0	0

* Accepted. + Withdrawn.

LONDON.—For alterations and additions to 1A, Sidney-street, Goswell-road, for Mr. Evans. Mr. E. J. Harrison, 70 and 72, Chancery-lane, architect:—

Lilley and Lilley	£593	0	0
Burton	361	0	0
Houghton, E., and Son	337	0	0
Ward and Lambie	327	0	0
Holbrook	325	0	0

LONDON.—For alterations and repairs to offices, 60, New Broad-street, City. Mr. H. Riches, 3, Crooked-lane, King William-street, E.C., architect:—

Boyd, C. H.	£188	10	0
Osborn and Sons (accepted)	129	0	0

LONDON.—For rebuilding offices and ware rooms, No. 24, Lawrence-lane, City, for Mr. H. P. Edwards. Mr. Herbert Knight, 129, Cheapside, architect. Quantities by Messrs. Ruat and Young:—
Bailey, H. (accepted) £3,279 0 0

LONDON.—For alterations and additions to 33 and 35, Queen's-road, Peckham, for Mr. Josiah Messent. Mr. J. C. Reynolds, 30, Camberwell-green, S.E., architect:—

THE DECORATION OF BUILDINGS.

VERY hazy ideas of the principles of ornament as applied to the decoration of buildings prevail amongst the profession. The fact is, that almost anything is thought to be decorative which has a certain degree of repetition of form, or contrast of colours. A stencilled frieze or a powdered wall, any repeat of a senseless pattern; a little colour and gilding, equally devoid of harmony, is called "decoration." And why? Form and colour appeal to most minds in very much the same way as religious sentiment or music does. Everyone thinks that he understands all about it, and that his own notions of what ought to be are right, notwithstanding all that artists and scholars of every age have done and said to the contrary; and we have now as much bigotry as to what is good and bad ornament as there is in matters of theological belief as to which is the right and wrong. These people are like those text-idolaters who will see nothing beyond their own narrow view of what suits them the best, and who refuse to learn anything of the great past, or the history of the means by which the documents or laws have been formed and handed down. They take to a certain theory of ornament or colour because they know no other, or have made few inquiries as to the different schools that have existed; but all this confusion has arisen from the great "split-up" of the arts, and the notion since current that art and ornament are things apart altogether from utility, and that ornament of any kind can be applied to an object or a building, as an ordinary person without any taste might paper a room and call it decorated.

Perhaps we cannot wonder so much at the general ignorance on questions of art when we consider the number of different ideas put forward by theorists; the want of a knowledge of the principles, and the vague and indefinite teaching that has been followed. When we see one scheme of decoration, say, for a vestibule or a room, totally different to another, both in the kind of pattern and the colour, employed in the same building, we are constrained to ask Which is the right principle? Each decorator can explain in his own manner the principle which has guided him. They cannot both be right, and they may be both wrong. For example, in wall decoration we may have a paper in which the diagonal distribution of pattern as a diaper is adopted in one room, and another of the same height and proportion on which the vertical arrangement of ornament is marked. They cannot both be based on right principles. Or, again, we see one design in which the parts are balanced, another in which they are scattered over the surface. The dogmatic assertions of professional decorators cannot be refuted by the public who pay. Like rival medical theories, they admit of no solution, except that in the latter instance there is the orthodox theory to fall back upon, whereas in ornament the followers of one school are almost as powerful as those of another. One repudiates the other, and the young student is puzzled by the contradictory opinions he finds in books no less than by the absence of all law and principles he finds in actual examples. As an instance, how can he accept, without considerable limitations, the utterances of the two opposite schools, the naturalistic and the conventional? By one we are explicitly told that exactly in proportion as the reference to nature becomes more direct, the art becomes

noble; by the other, that foliage and flowers, as subjects of decoration for our surfaces, are wrong in principle, and degrading. All this is very puzzling, and we cannot wonder that so many efforts by our chief decorative artists should be so completely contradictory and confusing. Modern decoration has failed to harmonise with our great architectural edifices, owing to the want of a general agreement. So long as we tolerate mere literalism which copies nature and applies it as decoration, we cannot expect to find any great ornamentalist such as those which graced the period of the Italian Renaissance, for such a system neither implies invention nor imagination. All ornament must be more or less conventional, and there has been no art without convention. Even the realist when he succeeds uses the very means he affects to despise; he has to adapt a leaf or a flower to a given position, and to treat it after the manner of the material, whether it be of wood, or stone, or metal, or textile fabric. The new directory of the Department of Science and Art gives some advice—good as far as it goes. It deduces laws of ornament from the observation of nature, and of good ornament it shows that the parts of plants are set out on a geometrical basis seen in the section of stalks, buds, fruits, &c.; and in the plans of flowers, that the arrangement of leaves and flowers are also on a geometrical basis. Keeping this law in mind, the ornamental artist can develop it, always bearing in mind the fitness of ornament for its place. We are glad to admit that we do not see such monstrosities now as baskets of fruit on carpets, or modelled representations shaded up on wall-papers; but we find still a want of conventionalising power, which implies a study of plants and flowers and other organic objects. Many designs we see for decoration show a total absence of anything like adaptation, or the selection of the right plants for particular purposes. The material ought to suggest the kind of plant. For textile fabrics, such as cottons and muslins, the delicate growths like poppies, grasses and ferns, and light flowers are certainly more appropriate; for wood and stone, the oak and similar massive plant forms. Adaptation should not overlook the character and growth of the plant. Some leaves and flowers are more suitable for horizontal, some for vertical positions, as they show in their growth these tendencies; other plants and flowers are better for large surfaces of walls, or ceilings. These are principles necessary for all decoration, whether realistic or conventional, and in this wider sense, indeed, all ornament must be natural. Only our great decorative artists have the ability to select the most appropriate and beautiful folial and floral forms, to abstract from them all that is characteristic, and adapt them to the material and position; and for modern examples we may point to the works of Morris, Burne Jones, Crane, and their followers. Panels and inclosed spaces, bands, and friezes are too often left to the taste of the painter or so-called decorator, who is content to fill up the space with meaningless scroll-work, honeysuckle, frets, and other conventional ornament. Whether a panel in a wall or a ceiling, the space is one requiring a skilful arrangement of lines, either of straight lines or curves. The student will find this subject analysed and treated in Mr. Lewis F. Day's "Planning of Ornament," and in Mr. J. Ward's "Principles of Ornament," edited by Prof. Aitchison, A.R.A., from which he may derive some assistance. Persian borders and Italian cinque-cento pilasters and panels, are the best examples to follow, though for plain surface ornament the Saracenic or Moorsque diapers are very appropriate. How many abortive attempts one sees in the mural decoration of churches, devoid of all character and scale. Chancel walls are sometimes decorated by diapers, checkers, and powdering,

but are so mechanically done that they only produce monotony and disappointment when viewed close. The scale is often too large. We are glad to find the subject of the application of ornament in architectural decoration is to be taken up in a course of lectures by Mr. Hugh Stannus, F.R.I.B.A., at the University of London.

Then, also in colouring we find a total disregard of any laws as to primaries, secondary and tertiary colours. How seldom we find the painter-decorator has studied anything but his own taste in selecting the colour or paper of his wall, quite oblivious of the particular tone complementary to the remaining hues employed. The architectural decorator has most to do with secondary and tertiary scales. Citrons and russets and terracotta tints have all their proper relation with their complementaries, which ought to be present, and the tone of each should be balanced by the other colours to produce harmony. We often see a reddish terracotta without its corresponding complementary, the effect of which mars the whole scheme of colour. One colour happens to be in excess, and the whole harmony is destroyed.

SOUTHWARK LIBRARY COMPETITION.

THE designs now on view at the vestry hall, Borough Market, for the proposed public library are seven in number, and show some good, if not ingenious, planning. As we stated last week, the Library Commissioners have given the first premium to Mr. John Johnson, of Queen Victoria-street; the second premium has been awarded to the design of Mr. H. Hardwicke Langston under the motto "Well Lighted," and the third premium to the design of Mr. S. R. J. Smith under the motto of "Q," but we are not informed which design is likely to be carried out. The site is nearly a square—a corner plot situated between Southwark Bridge-road and Union-street, both of those frontages being open. Mr. John Johnson's design places the main entrance in the centre of Southwark Bridge-road front, with the librarian's entrance at the south end, between which entrances is the committee and librarian's room, 19ft. by 15ft. The public hall is spacious, and the lobby and staircase behind the librarian's room derive their light from a skylight. The newspaper room, 57ft. by 23ft. = 1,311ft. super., is ranged along Union-street on the north side, and lighted by six side-windows, besides one at the end; the lending library is in the rear, 37ft. by 34ft. 6in., with the borrowers' lobby in front of main entrance under the staircase. Glazed partitions dividing these rooms are shown, supported by piers or iron columns, which are also introduced between the news-room and staircase-hall. Coil cases are shown for heating along these partitions, and the tables of newsroom are placed crosswise in two rows, each for ten readers. The lighting of the lending library has been effected by a skylight along the rear portion of the room, and by setting back the west boundary wall on the upper floor, the same wall being carried by iron columns in the lending library—an arrangement that is necessitated by the premises built up to the site on the west side. The first floor shows a large reference library extending over the lending library and end of newsroom, 34ft. by 18ft. and 23ft. by 37ft. A youths' reading-room, 23ft. by 19ft. 6in., occupies the front portion at the corner of the two streets, and a suggested magazine-room is placed over the librarian's room and hall, 33ft. by 20ft., with a bay window over the entrance. The staircase is separated from this room by a glazed partition, and a similar partition separates the reference library from the youths' room.

Although the arrangement is compact, there is rather a cramped landing, and the attendant's room would have been more desirable in a central position below. The second floor is given up to the librarian, except the rear portion, which is roofed over. The front elevation is in an ornate Italian style, with a small clock turret over the entrance, but the fenestration and pilasters have a crowded appearance, and we think too much elaboration has been attempted, as in the angle pinnacle at the corner of streets. The Union-street façade is even less pleasing on account of the drop in the roof level. "Well Lighted," by Mr. H. H. Langston, nephew, we hear, of the clerk of the Commissioner, has a centre public entrance in the main frontage leading to a central square hall, with staircase on the left. On the right hand is the newsroom, 34ft. by 27ft., lighted in front and along the Union-street side. The lending library on the rear side has its entrance and lobby facing the hall, and is 50ft. by 24ft., with windows at the north and south ends, the latter obtained by setting in the outer wall on that side and by a skylight which forms a lean-to on the next floor. The private passage to library in connection with that official's entrance on south side is convenient. On the first floor the reference library occupies the space over the lending library and part of newsroom, and is 41ft. by 39ft. 6in., exclusive of landing out of one corner. In front are the youths' and ladies' reading-rooms. The reference library has a lantern light, besides end windows. The external treatment of brick and terracotta is simple, mullioned windows and gables in front, but the elevations have a bare look. The author puts the cost of the building at £4,000, and £1,000 for fittings. The stepping back of the building in the section on the south side has been resorted to for lighting the lower floors.

Mr. S. R. J. Smith's design, which takes the third premium under letter "Q," has undoubtedly the best plan. The entrance is in front at the Union-street end, with the librarian's at the corner; the entrances and staircases are compactly brought together with side-lights, and there is a step entrance from Union-street down to the basement—a very desirable access, unprovided for by other designs. An 8ft. entrance has the borrowers' lobby on the left hand, convenient for the public use, and the remainder of the front is the lending library, lighted by four wide windows, a wood and glass partition separating it from the newsroom, behind which is kept one story high and top-lighted; the cases and desks are placed crosswise. Opposite the entrance is the librarian's room. The first floor has the reference library in front, lighted by windows on the front and back sides, with a gallery round it, a lantern light being shown over the newspaper room. Above are the librarian's rooms. A spiral staff-stairs and lifts are shown. This design is accompanied by plans showing the fresh-air inlets under windows and foul-air extract flues at the ends, Tobin's tubes, and the gas and hot-water arrangements. The external design of three stories in front is of brick and terracotta or stone dressings. There is an order on corbels on the first-floor story, and an attic and high roof. The character is suitable for a library, the return side being of two stories, and the newsroom behind one story. There are two other well-studied sets marked "Q," by the same author; one of these has a centre entrance and hall arrangement, with the lobby on the left; a newsroom, 1,200sq.ft., on right side; and lending library on the left, top lighted, with librarian's entrance at the left corner of front. The reference library (1,500sq.ft.) above is along the front, with youths' room at back of stairs in Union-street in a return wing. Plain, but artistically treated, brick elevations, with elliptical

headed mullioned windows on first floor, are shown. A tower and turret break the outline. The front is set back over the ground story, forming a lean-to roof in elevation. The librarian's room is placed at end of hall on ground floor, thus insuring supervision. A third arrangement puts the entrance to left of front, with large hall and borrowers' lobby to right. The lending library forms a large square room, with windows in front and to Union-street, 1,200sq.ft., the counter projecting into it. The newsroom is at the back, occupying the whole length, and lighted by lantern, a wood-and-glass partition dividing it from hall and lending library. The librarian's entrance is in Union-street side, and is made to project into the lending library at the corner. The latter room is partly lighted by a lantern in the centre. The elevations tinted show a plain plastered front. "1 in a circle" is an artistic Italian design of the astylar type, of stone, with high-tiled and hipped roof, broken by lofty chimney-stacks. A bold eaves-cornice, with deep frieze in relief underneath, and the grouping of windows and a nice entrance doorway give a picturesque and pleasing effect. The plan has merit; the entrance hall and lobby are in the centre, with newsroom on the Union-street side, and a youths' room on the left of entrance, with a square lending library of one story occupying the south-west corner, lighted through a large circular domical glass roof. The reference library is placed along Union-street, with librarian's office and staircase hall above. The latter would be better on the ground-floor, and the domical roof of lending library would be a source of expense in repairing. "A" is another set of plans, the author of which has unwisely followed the oblique lines of side street in the walls, which spoils the plan. The elevation is not improved by the peculiar circular cornered windows divided by mullions.

It is probable the Commissioners may see fit to revise their decision before any steps are taken.

STABILITY OF WALLS ON SOILS.—VII.

Decrease of Unit-Pressure on Successive Offsets Downwards.

AS the area of each successive footing course downwards increases, the incumbent unit-pressure of their loads decreases in a corresponding ratio. Consequently the projection of the successive offsets, assuming them to be of material of uniform transverse strength, may increase in the proper ratio, or the thickness of the footing course may likewise decrease, as the transverse stress acting on the offsets is less at the bottom course than at the top course of the footings.

Fig. 16 shows a series of four-footing courses, numbered from the uppermost downwards. There is a proportionate increase of unit-pressure upwards from the bottom footing course of the foundations corresponding to the projection of the offsets. If the offsets vary in proportion to correspond with the changes of the unit-pressure on each successively, it will be inversely as the unit-pressure. Thus, if the unit-pressure be double, the projection of the offset would be the one half. It is not usual in ordinary practice to make any difference in the projection of the offsets; but in certain cases of massive walling or isolated piers, foundations for columns, stanchions, &c., the upper courses of the footings are made proportionately thicker than the lower ones. In extensive buildings, using flagstones for this purpose which are quarried at a great distance, considerable economy may thus be effected. The bottom course, in all cases, should be extra thick, on account of the difficulty and uncertainty of at all times securing uniformly solid bedding, especially when it consists of "landings" or flagstones of large dimensions, and likewise because of the weakening effect produced on some kinds of stone, brick, &c., by submergence in moist or water-logged soils.

Ratio of Changes of Unit-Pressure.—For the benefit of the tiro, the following example of the

decrease of pressure downwards on the footing courses may be useful. Assume the wall load W, Fig. 16, acting at its base to be 3 tons per square foot of its area. The position of the section giving this area is indicated by the arrow-point. The area of the cross-section at this point, if it be 2ft. wide, is 2sq. ft. per foot lineal of the wall; therefore $3 \times 2 = 6$ tons of pressure per foot run

FIG. 16.

of the wall. If the first footing course project 6in. beyond each side of the wall, making its breadth 3ft. lineal, and its area 3sq. ft. per foot run of the wall, then $6 \text{ tons} \div 3\text{ft.} = 2$ tons pressure per square foot over its area. The 2nd, 3rd, and 4th footing course projections add successively 1ft. to 3ft., making the respective footing areas 4, 5, and 6sq. ft. per foot run of the wall. These areas divided into the 6 tons give $1\frac{1}{2}$, $1\frac{1}{3}$, and 1 ton for the corresponding pressures. The above proportions will be seen at a glance in the annexed tabular form. Assume the position of the statical axis of the imposed loads to be indicated by the arrow W, Fig. 16, and that the entire projection of the lowest footing base on the left side of the arrow is divided into six equal parts, two of these projections are in the half-wall, and four of them in the successive offsets of the footing courses.

Area—	Ratio of Base Area.	Pressure in inverse ratio.
Of half-wall.....	= or $\frac{1}{2}$	3 tons per sq. ft.
„ First footing course =	or $\frac{2}{3}$	2 „ „
„ Second „ „ =	or $\frac{1}{4}$	1½ „ „
„ Third „ „ =	or $\frac{1}{5}$	1⅓ „ „
„ Fourth „ „ =	or $\frac{1}{6}$	1 „ „

The projections of the footings on the right-hand side of the figure are similar.

In practice, the proportions of imposed loads to the footing area must be corrected by taking into account the additional loads due to the weight of the materials of which the successive footing courses consist.

Transverse Distribution of Footing Areas.—The pressure of the weight of the wall itself, and of the imposed loads derived from roofs, floors, and special features of the engineering, structural, or architectural design, and from fittings, furniture, storage, live loads, or incidental loads or other source of accumulative weight or pressure, such as the vertical component of wind-force, &c., is discharged upon the footings. The static resultant of this accumulation of pressures marks the static axis of the wall; and when it passes down through the geometrical centre of the wall, the footings should project equally on both sides of the wall; but as this rarely occurs in practice, it is necessary in designing the footings to find the precise position of the statical centre, in order that the footings shall project equally on both sides of the statical plane of the wall. The method of accomplishing this will be considered further on.

Pier Footings.—In the case of isolated pier footings having projections on four or more sides, according to the shape of its horizontal section, the offsets must project equally from the static axis of the imposed loads. The projections must be proportioned to the area resulting from the all-round equal offsets of the successive footing courses when the static axis coincides with the geometrical centre of the horizontal section of the pier; but when, from necessity, arising from any incidental cause, the static axis of the imposed loads is eccentric to the geometric section of the pier, the disposition of the projections must

be governed by the static axis, and not by the geometric centre of the pier.

Rule of Thumb Footings.—It is a common practice in ordinary buildings to project the footings equally on both sides of the lowest portion of the wall as prescribed by the Metropolitan Building By-laws, 1855, first schedule, s. 8, and the Local Government Model By-laws with respect to new streets and buildings, clause 15. The projection of footings, as well as the thickness of walls for various heights and classes of buildings, prescribed as above, adopted at the instance of the late Joseph Gwilt, were based upon rules deduced from the extended observations and deductions of Jean Rondelet of many historic ancient buildings in various countries of Europe.

Story Offsets of Walls.—The usual offsets in the thickness of masonry walls, in brick walls 4½ in., which are made at the top of a story, according to the unsupported length of the wall and height of the building, alters the statical centre of the entire wall from the geometrical centre of the lower portion of the wall from which the footings project. This shifting of the static centre, so far as the wall alone is concerned, is sufficient to make a difference in its static stability when supported by a compressible soil. But, added to this eccentric loading is the difference of the leverage action of the abutting weights of the floors, roofs, &c., which have their bearing on these different receding thicknesses of the wall in the several stages of its height. This geometrical centre of the basement or lowest portion of the wall, which is thus usually taken as the haphazard guide to transverse distribution of the footing courses, is done without any regard to the eccentric leverages imposed by the various sources of loading at the different receding points of their application in the height of the wall. In addition is the further eccentricity which may be produced when the wall is faced with stone or with pressed brick, in either case much denser than the brick backing and filling forming a portion of the structure of the wall, as well as any stone dressings more or less projecting from the face of the wall. Hence the only accurate method to treat the transverse distribution of footings is to ascertain the statical centre of the loaded wall, and to arrange the footings to offset equally on each side of it. The computations for this purpose need not be such an elaborate matter as it would at first appear to the tiro, for the facility increases with the practice of adopting exact methods of estimating, and with their repeated use. Were this done oftener, there would be fewer cases of walls being out of plumb.

Mathematical Rigidity Not Practicable.—In speaking of rigidity with reference to materials of construction, it should be observed that the abstract rigidity of the mathematician, in reasoning about the action of forces upon rigid bodies, disregards all the natural properties of materials. But in applying this line of reasoning to practical structures, the action of the properties of materials through which forces are transmitted or applied, and also the action of the properties of the materials receiving these transmitted or applied forces, must also be considered. All constructive materials are liable to yield more or less to the action of external forces according to their natural properties and the direction in which it is applied, and of the reactions thereto; if transversely, it produces bending (breaking), shearing, and distortion, or, if in a longitudinal direction, it produces stretching (tearing) or contraction (crushing).

Centre of Gravity within Crushing Limit of Supporting Edge of Masonry.—The practical supporting resistance of the materials of the foundation to crushing or rupturing when the weight of a structure is concentrated upon its edge must not be exceeded. In general this is accomplished by keeping the centre of gravity of the mass within the middle one-third of the base. Considerable overhang of a structure may thus take place without incurring danger. Thus, in the case of the Leaning Tower, or Campanile, of Pisa, in Tuscany, the main cornice, which projects 2ft. 6in. from the entablature, overhangs the base 13ft. 8in.—i.e., 1ft. 2in. of a leaning beyond the vertical. The tower is 53ft. diameter at base, and 52ft. mean diameter. The height to the top of the belfry is 183ft. The basement is supported on 15 columns, and is surmounted by six arcades with 30 columns each. Above the top arcade rises the belfry, 27ft. high and about 40ft. diameter, having 12 columns. The main

cornice of the horizontal entablature of the seventh story (counting the lowest story as the first) is therefore 155ft. above the ground level. The overhang of the wall is therefore about one horizontal in 13.88 vertical. The lower story walls are 13ft. thick; the seventh story wall is about half of that thickness. The tower is constructed throughout of marble. The centre of gravity of the wall on the overhanging side is about 5ft. within the edge of the footing. The centre of gravity of the mass is about 17ft. further in, and is about 7ft. out of plumb—that is, it lies within the middle third of the base. To secure stability in the above conditions, the safe supporting power of the soil must not be exceeded. The materials and mode of construction must also be sound and durable.

Bond-stones in Masonry and Brick Piers.—We frequently observe slender piers of brickwork, which sustain heavy loads, to be built without bond-stones covering their entire cross-section at suitable intervals in their height. When there is a maximum unit pressure upon the pier, such bond-stones serve to equalise and transmit the pressure over the entire area of the section throughout its length, and thereby prevent splitting or fracturing. Special care should be taken to impose the loads upon such piers exactly central, so as to be transmitted down through its vertical axis. If loads act eccentrically upon a slender pier, or column, or stanchion, its strength may be reduced to about one-third of its normal strength, which reduction, therefore, may cause failure of the structure, with more or less disaster.

Stability of Masonry Walls: Empirical Deductions.—Stability of buildings depends not only on the stability of the foundation soil for loads acting vertically through the axis of the supporting base, but also on the prevention of loads or forces acting eccentrically or obliquely thereon. This broader condition of stability implies that loads should be centralised axially on the wall or pier, and also that the wall or pier should possess inherent stability of its own to prevent fracture or deflection. Stability of the wall or pier has been empirically assignable by Jean Rondelet in specific degrees, according to the nature of the purpose it is intended to serve. Thus, for the walls of forts, towers, strongholds, stability depends on the massiveness to resist heavy percussion and penetration of missiles and projectiles. For mills, factories, workshops, and buildings in which heavy machinery is in motion, it depends upon a scientific disposition and concentration of the masses of materials at suitable points, so as to readily absorb the vibratory momenta. In dwellings, office buildings, and warehouses the stability of walls is principally dependent upon their ability to resist vertical loads; but in the case of high or prominently exposed structures, it is also liable to the leverage force of wind-storms. Some authorities, as Rondelet, have assigned three classified degrees of stability to independent walls, thus: 1. Those having the least admissible thickness, assumed at one-twelfth of their height, when the stability is not reinforced by cross-walls, floors, &c.; 2, those having a medium safe proportion of thickness to height, which is assumed at one-tenth; and, 3, those having undoubted stability as obtained when the thickness is one-eighth of the height. These proportions are purely empirical. It is assumed that the quality of the materials, the character of the construction, and the class of the workmanship are all of the best for the purpose. The stability of walls also depends on the adequacy of the foundations, and of the supporting power of the soil. In buildings which have cross-walls the Metropolitan Building By-laws, 1855, permit a reduction of the thickness ranging from one-thirteenth to one-sixteenth of the height of the wall.

(To be continued.)

ARCHITECTURE AND BUILDING CONSTRUCTION AT KING'S COLLEGE.

THE younger readers of this journal who are anxious to pursue any branch of their professional education, to qualify for Institute or other examinations, or who wish to complete their knowledge of building construction, will be glad to know of the classes now opened to them at King's College, and something of the facilities for study that are now given at that institution. Considerable additions have been made, as we hinted last week, to the museum and studios of

this architectural school since Professor Banister Fletcher was appointed to the chair. Last year a joint committee was appointed of members nominated by the Council of King's College and by the Court of the Company of Carpenters, and they instituted a scheme which, we believe, has worked well. The Carpenters' Company provided cases of specimens, diagrams, drawings, and wood models, which have been largely supplemented by purchases of valuable casts and drawings by Professor Banister Fletcher. The building trades have liberally contributed to the Museum of Building Construction. The day and evening classes in building construction and architecture have been well attended, and ought to be largely patronised by students. There are also classes for drawing and design, and the Carpenters' Company school for wood-carving ought to be mentioned, a large room being specially equipped for this purpose. Medals, prizes, certificates, and money prizes are annually awarded for these several subjects. The carpenters' and other workshops are replete with tools, apparatus, and models, so that pupils or young men may avail themselves during or after their terms of articledship of these indispensable facilities to learn the special crafts allied to their profession. We recommend every student to obtain the syllabus and particulars of these classes and the prizes that are awarded, which comprise the gold medal of the Carpenters' Company awarded at the end of the course of building construction and architecture in each third year, and Mr. Arthur Cates' annual silver medal.

In looking over the catalogue of the Reference Museum, a new edition of which is just issued, and which shows a collection of over 2,500 architectural illustrations, casts, constructional diagrams, photographs, models, and specimens, a faint idea may be gathered of the extent and scope of the instruction given in architecture and building construction at this college. Professor Fletcher has incurred a large expenditure in selecting illustrations and equipping this invaluable storehouse in which he has been aided by his son, Mr. Banister F. Fletcher. Students desiring a knowledge of the styles cannot possibly do better than consult this museum. The illustrations include plans, sections, diagrams, and casts of each great style—Egyptian, Assyrian, and Persepolitan; Greek, Roman, Romanesque, Byzantine; French, Italian, German, and English Gothic, the Renaissance, Saracenic, Chinese, and Indian timber architecture, &c. These illustrations are all numbered for reference. We do not know where a more comprehensive series of views, plans, and details of all the great Classic temples may be seen, in addition to casts from the actual edifices, of capitals, friezes, panels, and details. What, for example, can be more instructive than the large Doric capital of the Parthenon, and the beautiful Ionic capital from the Erechtheum in the professor's lecture-room?—where may also be seen the cymatium moulding to architrave of the latter, the enriched echinus, the antefixæ ornament from the Parthenon, and a variety of other Greek casts illustrative of the finest period of Hellenic architecture. Drawings and book illustrations may give fair notions, but the full-size cast enables the student to appreciate the actual mouldings in the "round," and the subtle effects of light and shade and reflection. Thus the skylight in the rooms throws the light down upon the capitals we have referred to in the natural manner. Ornament in relief, as in friezes, panels, foliage in capitals, &c., can only be realised to the eye by casts. The English Gothic series of casts contain many of the finest specimens of Norman, Early English, Decorated, and Perpendicular detail, and many of these are hung in the corridors and on one side of the professor's lecture-room. Some fine casts of Renaissance detail from Venice, Florence, and other Italian cities are to be seen, absolutely necessary to the student of this period who has not pursued his studies on the Continent. The constructional diagrams and models form an equally important part of the collection, and these are drawn to large working scales. Thus the details of roof trusses give every part of the construction; the framed floor is equally well explained by enlarged details; and such complicated branches of joinery as boxing shutters, deal-cased frames, panelled doors, details of staircases and hand-rails are illustrated in a manner that no textbook can pretend to do. Complicated timber structures, like timber turrets and steeples, church roofs, domes, and lanterns, and examples of roofs like

those of N. Petherton, Somerset; Long Sutton Church, Guesten Hall, Worcester, Croydon Palace, Staple Inn, &c., are illustrated. Stone, brick, and iron construction and fireproof floors on different systems, including Dennett and Ingle's, Doulton and Peto's, Homan and Rodgers', Lindsay's, Fawcett's, and other recent plans are of immense value to the student. We have before us as we write a very admirable series of photographs just taken by Bedford Lemere and Co., representing the professor's lecture-room, the architectural studio, the corridor, and wood-carving school, which give an excellent idea of the museum and appliances at King's College, including the valuable series of plaster-casts, drawings, and photographs. The models illustrating the elementary operations of building such as bonds of brickwork, floors, roofs, joints in joinery and ironwork, and the specimens of materials, ought to be seen to fully appreciate the practical value of a course of lectures at King's College, where canons of art, precept and principle, of construction are visibly brought to the eye and hand of the student, and where he can "handle and see" what actual construction is.

NOTES FROM EDINBURGH.

THE new Municipal Bill, of which notice is to be given for the coming Session of Parliament, has now been put into nearly final shape, and though it embodies some miscellaneous civic affairs, is mainly an improvement scheme, involving the removal of insanitary tenements upon a larger or smaller scale, widening of thoroughfares, and opening new streets in congested districts. If the provisions sanctioned by the Council are carried out, as they will doubtless be, either under powers obtained by the Bill or the existing Acts for improving the dwellings of the working-classes, the operations resulting will be extensive, going on for six or seven years, and will keep the wages of the builders at their present high-water mark for some time to come. The alterations touch the High-street and districts south of that line, and include no portion of the City on the north. Closes in the neighbourhood of the Lawnmarket will have more light and air, the Cowgate and Westport will be widened at very necessary points, and a new street formed between Earl Grey-street and Gillespie-crescent. These useful changes will not greatly affect the architectural aspect of the portions of the City best known to its admirers; but the improvement at Bristo-street will open up to view the new University Hall, to which the old tenements are in far too close proximity. The amount of expenditure is to be limited to £157,000; but experience of other improvement schemes points to a much larger outlay, which the rates will be called upon to discharge, £8,000 being assumed as the City's share of the annual equivalent grant, and security for repayment of the amount scheduled in course of thirty years. The work under the last improvement scheme, which cost about £400,000, was only recently completed by the erection of tenements in Jeffrey-street. The provisions of the new scheme are, indeed, but an instalment of work that never ends, and many proposals, such as that for widening or rebuilding the North Bridge, purchasing the Music Hall, new municipal buildings, &c., are relegated to a distant future. Sanitary improvements are considered of more essential moment, and it must be allowed that the effect of the last improvement scheme is most encouraging to persevere, the death-rate, with exception of last year, having been reduced from 25 to 18 per 1,000.

The present Lord Dean of Guild, who is a civil engineer of standing and experience, has taken a deep interest in his official duties, and given to the public an interesting historical sketch of this department, and an analysis of its procedure. The new Bill will make provision for remedying some defects of the procedure, and give greater powers to prevent the erection of insanitary houses of smaller size—1,000c.ft. being taken as the minimum for houses of one apartment. The height of tenements will also be better regulated. Nothing is proposed in the way of extending the powers of the court over the details of architectural style. But something might well be done in this direction. The south approach to Edinburgh in the line of Minto-street has always been noted for its ample width and beauty of the fringe of garden ground re-

lieving the somewhat formal range of self-contained villas. This point of vantage is being ruthlessly destroyed by the shopkeeping element, and ere long the whole of the east side will be shut up behind a screen of the most heterogeneous and discordant elevations. Shops and shop-front architecture, generally designed by the contractor, are, as a rule, erected without any knowledge of the style from which details are taken, and many curious specimens are thrust upon the eye, which would be more offensive had the windows no better attractions than their architecture—which is truly the architecture of the window.

Matters at their worst, however, generally mend; and something to good purpose, it is to be hoped, has recently been done to improve the prospects of good architecture and the taste for it in the formation of a new art school, which will stand in the same relation to the similar school now for many years carried on by the Board of Manufactures as the University bears to the ordinary School Board school or others of like character. The attempt to enlist the sympathies of the R.S. Academy in favour of a course of instruction for advanced pupils in the scientific study of art in its varied practical applications utterly broke down. The result has been the formation of this new scheme, which has found sufficient patronage in the way of subscriptions to make a beginning this year. The object in view is to impart information—in the principles of artistic design—in architecture, sculpture, carving, and decorative detail in all the industrial trades. Rooms have been granted by the Board of Manufactures, very suitable for the purpose in view, being the rooms vacated on removal of the Antiquarian Museum to its proper home. Classes will be regularly formed, and occasional lectures given on the higher aspects of the various subjects. Dr. R. Anderson has been engaged to find a good selection of casts, models, &c. The student will have new library and travelling scholarship, and bursaries to stimulate their efforts. The advantages of such opportunities of acquiring information by methods so much superior to the haphazard study of principles of art embodied in a perplexing multitude of books, many of which are difficult to procure, are incalculable, and if the scheme is supported as it deserves to be, there can be little doubt of its meeting a want of which the architectural student has had much reason to complain.

The new University Hall is making progress with floor and roof. The basement chambers, lined with white glazed brick, are completed, with the heating apparatus, consisting of a series of vertical steam-pipes, placed on each side and immediately in front of the space beneath the platform. The ceiling, which is of timber, is only a little way towards completion, and the eye of the dome is still unglazed.

The new West Kirk is so far advanced as to be ready to receive the roof. It bulks much more largely in the landscape than its precursor, which was of goodly size, and with its large apse and transept projections has, from the Mound, a look of St. Peter's about it, which well becomes it as the Mother Church of the modern city. There is nothing in the style finally adopted of very ornate character, and as the walls are well-dressed rubble work from Hailes quarry, with simple white stone dressings, the semi-rural situation of the edifice has been carefully respected, and when completed, the superiority of this method to a design in polished ashlar will be still more conspicuous. Though somewhat low, the site allows of the building being very fairly seen on its upper part from the high level of the streets adjoining.

Another very conspicuous addition to the architecture of Prince's-street is to be seen in a nearly completed state at the other end of the thoroughfare, and arrests the eye, on entering from the Waverley station, by force of contrast to all other architectural elevations. It comprises business premises and shop-front, confined within the narrow limits of one of the old original tenements, with the large frontage of the Edinburgh Hotel one side, and a very much lower one on the other. The style is in the main Late Decorated or Perpendicular Gothic, with great superfluity of surface cusped arcaded decoration, and fantastic arrangements of details, with eaves, cornice, and some other details of pronounced Classical design, built in courses of red and white stone, with crocketed finials shot up into the tops of the windows, which are devoid of

cusps. A large shop-window of elliptic form is the most conspicuous feature of the ground floor, and its arch-moulding has been decorated with Gothic square leaf ornaments—much too large, and looking dangerously near the point of dropping off. The whole speaks more eloquently of the skill of the draughtsman than the designer.

The days appear to have arrived when architects, as well as other trades, must advertise. The Empire Theatre of Varieties, now nearly completed for Mr. Moss in Nicolson-street, is situated behind the street, a huge brick building, but has its entrance to the street emphasised by the erection of a small square tower, with copper dome, in Moorish Gothic, surmounted by a large figure, in heroic size, of what appears to be the tragic Muse. The public are informed in large letters of the fact that Frank Matcham, Esq., London, is the architect. The interior is spacious, and tastefully decorated in so far as plaster-work can make it so.

WOOD VAULTING UNDER RINGERS' ROOM IN THE TOWER, WINCHESTER CATHEDRAL.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THE date of this vaulting is told in the inscription round the inside of the bell-hole: SINT DOMUS HUJUS PII REGIS NUTRIIT REGINAE NUTRICES FIE (May pious kings and pious queens be the foster-parents of this church), the large letters standing for 1634. The bosses, except two, which are modern, are carved as emblems and memorials of Charles I. and his time. If a suggestion, long ago made by the cathedral architect, Mr. John Colson, were carried out, and the lantern—which now makes a miserable belfry—restored to its original use, this flimsy "chip-vaulting" might be fixed at the

top, in which position the overpowering bosses would be less prominent, and the graceful fan-ribs would spring more freely unstraightened by their badly-fitted panels, whose features would be dimmed, if not lost, at the more distant height.

R. L.
[The words, "threatened with destruction" were inserted on our plate under a misapprehension, and we are glad to find that the information sent us is, so far, incorrect. The vaulting is only to be removed and refixed at a higher level.—Ed.]

BRICKS AND JOINTS IN BRICKWORK. No. I.

THE writing of these articles was suggested by a recent case at arbitration before Henry Currey, F.R.I.B.A. as arbitrator, extending over three days, chiefly on the subject of joints in brickwork, and in which the writer was a witness. It is only in such cases as the above that a profuse knowledge of in themselves small practical matters are properly valued, a statement advanced lest this and the articles to follow should be thought unnecessarily profuse in detail.

For some few years past the London stock proper has had a rival in the brick market, in the shape of the Fletton brick, advertised as a superior stock brick, the interior work of the General Post Office now building being of these bricks. The first quality of Fletton bricks are unquestionably good, well-finished bricks, possessing the qualities and characteristics in make peculiar to most pressed bricks—viz., density or compactness of structure, weight, sharp well-defined arrises, and well-finished faces, combined with truthfulness of form. These bricks, like most others, vary much in quality, the inferior kinds being known to the practised eye by a condition which in the ordinary London stock brick would be described as "shuffy," derived from the word "shuff," applied to the most inferior class of bricks produced by clamp-firing. The Fletton brick, however, being made under entirely different conditions to that of the ordinary stock, and being kiln-burnt instead of clamp-burnt, is much above the level of the "shuff" proper found in stock bricks. The edges of such of the Fletton bricks are broken

away, the beds of the bricks having a general appearance of a want of cohesion, and when broken in two presenting a loose and frequently a cracked section, showing the bricks to be made from a strong refractory clay, which, in such particular instances, has not been sufficiently pugged, an evidence of which, in the shape of core or stones, is sometimes found in these bricks. The writer has known instances of core in some of the best clays breaking the shafting of the pugging machine during the process of tempering the clay. Mr. Kirkaldy has reported very favourably of the Fletton brick with respect to its resistance to crushing; but for exterior facings, as compared with stock bricks, it has the disadvantage of not having been in use sufficiently long (at least, in the Metropolis) for an opinion to be safely expressed as to its weathering capabilities. It is well suited for interior facings intended for distemper; but for plastered walls its smooth face, the result of being pressed in a metallic mould, does not afford the same amount of clinging surface or "key" for the plastering as an ordinary London stock brick. It may be said that the rough cut mortar joints over the whole area of the wall afford sufficient "key" to uphold the wall plastering in position, irrespective of any adhesion on the faces of the bricks. In cases of this kind it is safest to judge by comparison. Fletton bricks are cheaper than good London stocks, and take less mortar in building, a consideration which accounts for the London builder being an ardent advocate of their use.

Some specifications provide against the use of bats in the walls unless occurring as legitimate bond, which practically means the exclusion of

the use of bats, the cases in which they would be required as legitimate bond being few indeed. The clause may also be understood as one of these conditions or guards with which the architect finds it necessary to hedge himself about when dealing with the modern competitive builder, in some instances remarkable for his astuteness in finding out the weak points of a specification, and bringing his sharp practice to bear on them with a view to prospective extras as a means of pulling him through on a low-priced bill of quantities, and whose idea of building seems to be the throwing together of so much crude or wrought material, as the case may be.

The quantity of bats in a freight of bricks is generally a good criterion as to their hardness, provided the bricks have been loaded fairly from the clamp—that is to say, taken fairly as they stand without sorting. The softer bricks get very much broken in the different operations of handling in transit to the job. Another surer sign of soft inferior bricks is the great amount of brick-dust present in the bottom of the cart or boat when unloading the bricks, due to the attrition of their soft faces, good, hard bricks making little or no dust; a large amount of dust present at once exciting the suspicion of the practical man as to the quality of the bricks. In a recent case at law in connection with the roofing-tile trade it was contended, and ultimately ruled, that $2\frac{1}{2}$ per cent. of defective tiles is the recognised maximum quantity allowed in every freight. A similar rule, by tacit acceptance, we believe applies to the quantity of bats in a freight of bricks—the maximum proportion being two bats to every four unbroken bricks—

or, using a term of the trade, two bats to every "hand of bricks," the bricks, for convenience sake, being handled five at a time, the two bats counting as one brick. In this way 80 per cent. of whole bricks are obtained. The use of bats is often a vexatious question, and the cause of much friction on the building between the representative of the contractor on the one side, and the representative of the architect on the other. A practice of the writer in the supervision of brickwork is not to object to the use of bats if three whole headers intervene between every two bats, by which arrangement 75 per cent. (seventy-five per cent.) of the heading courses are whole bricks. But with every alternate header a whole brick, no danger need be apprehended under ordinary circumstances of building, provided the work be well flushed up every course, for brick walls are seldom, if ever, found to fracture longitudinally, for two reasons—viz., that fractures in brickwork are, as a rule, due to defective foundations, which defects generally show themselves in a direction transverse to the wall; and that the longitudinal bond or lap of the brickwork is only 2½ in., while the transverse bond or lap is 4½ in. The weakness of a wall, and of its foundations, is in a line at right angles to its line of direction, or the line in which the least resistance to fracture is offered. Large walls and piers are too often regarded by the builder as legitimate receptacles of the smaller material of building—an idea not alone peculiar to the bricklayer, nor to present-day practice, but one also held—in some instances at least—by the Medieval builders, who built their great hearts into the sculptured stones, and evidence of which may be seen in the remaining ruins of St. John's, Chester, and in the account of the survey of Peterborough Cathedral by John L. Pearson, in which he assigned the dangerous condition of the tower to be due to the fact that the great piers were little better than cased masonry filled in with rubble or unbonded stones.

A NEW CLOSET-SEAT.

WE beg to call attention to a newly patented closet-seat and bath top manufactured by Messrs. Wright, Sutcliffe, and Son, brassfounders and sanitary engineers, Globe Sanitary Works, Halifax, which possess many sanitary advantages. The closet-flaps are made in mahogany, walnut, pitchpine, or other woods, but the lower flaps of the seats and the surface of the bath tops are covered with a tough, waterproof, non-conducting material freed from all impurities by being subjected to a chemical and mechanical process. The advantages claimed are that the seats are warm, soft, and comfortable, that they are not affected by scouring or washing, are non-porous, durable, and tend to influence a cure in such cases as rheumatism, lumbago, sciatica, hip disease, &c. The tops do not crack, and for baths we should say this soft, non-porous surface must be a boon superior to the polished or varnished wood used for the purpose. The size and shape of these tops can be made to any paper template. Several examples of hinged seats and bath tops are illustrated. These are of polished mahogany, walnut, or pitchpine backs, with side hinges, showing the patented material over the actual seat made to match in colour the wood. Self-lifting hinged seats are also made with lever and weight, and the price ranges from 14s. to 25s. Sutcliffe's patent sanitary w.c. seats and bath tops will be welcomed by all invalids and those afflicted by rheumatism.

PRIZE DISTRIBUTION AT KING'S COLLEGE, LONDON.

THE annual distribution of prizes and certificates to the students in the architecture and building construction classes and the wood-carving classes at King's College, the trade classes at Chapel-street, W.C., and the amateur classes at Kensington, W., took place last (Thursday) evening at King's College, Strand, when there was a large attendance of students and their friends. The chair was taken by the principal, the Rev. Henry Wace, D.D., who referred to the substantial pecuniary aid afforded to these classes by the Carpenters' Company, remarking that had it not been for the support thus given, it would have been impossible for the college to have established evening instruction in building construction, constructional drawings, or the architectural studio. He mentioned that even the outlay on the wood-carving studio had been met by the Company, who also found all the money necessary for carrying it on, including the prizes. He had much pleasure in adding that the Carpenters' Company had promised to allot during the forthcoming year £200 each to King's College and University College.

Mr. Seymour Lucas, A.R.A., then delivered an address to the students, in the course of which he remarked that, as one of the judges, it had given him great satisfaction to note the evident progress of the students at King's College; but he had been particularly struck with the excellence of the work turned out at the Chapel-street classes, where both the models and drawings surprised him by their technical qualities. He then distributed the prizes in accordance with the following list:—

FIRST YEAR.—A. W. Makovski, £4 and silver medal; R. O. Fieldon, £3 and bronze medal; F. Clark, £2; Wearing, certificate of distinction; H. J. Mather, certificate of distinction; W. H. Gurney, certificate of approval; S. E. Trill, certificate of approval.

SECOND YEAR.—Trimmell, £4 and silver medal; Allberry, £3 and bronze medal; E. C. P. Monson, £1; H. T. Adlard, £1; A. G. Dixon, certificate of distinction; T. A. Watson, certificate of distinction; F. W. Bateman, certificate of approval; A. A. Dixon, certificate of approval.

EVENING CLASSES.

ARCHITECTURE AND BUILDING CONSTRUCTION.—S. Jefferey, silver medal and £4; E. C. P. Monson, bronze medal and £3; J. R. Johnston, £2; C. T. Aston, certificate of merit; F. C. Higgins, certificate of merit; T. C. Yates, certificate of merit; H. M. Lawson, certificate of merit.

CONSTRUCTIONAL DRAWING.—C. T. Aston, £3; S. Jefferey, £2; A. C. Long, £1; F. Mayell, certificate of merit; F. C. Higgins, certificate of merit; H. M. Lawson, certificate of merit.

QUANTITY CLASS.—Woodward, £3; E. Searchfield, £2; H. C. Cregeen, £1; S. Jefferey, certificate of merit; J. R. Johnston, certificate of merit; H. Allberry, certificate of merit; P. Ross, certificate of merit.

STUDIO.—Pearce, silver medal; Jordan, bronze medal.

Professor Banister Fletcher, J.P., F.R.I.B.A., in proposing a vote of thanks to Mr. Lucas, gave some encouraging statistics as to the progress that was being made by the classes at King's College. He observed that in the session 1890-91 there were 25 students attending the lectures and 11 in the drawing-classes; these numbers increased in the next year, 1891-2, the session just completed, to 30 at the lectures, 19 at the two classes on construction, 29 at the quantity class, and 4 at the studio. For the new session, that of 1892-3, 38 had entered for the lectures, 30 for the constructional classes, and the applications for the quantity-class, studio, and the wood-carving classes, which had not yet recommended, were all larger than in previous years. The new work for the present year included preparation for the examinations of the Sanitary Institute. Not only were the classes developing, but the library had been increased from 1,300 to 2,500 volumes during the year, and it would be seen that a series of architectural photographs to large scale had been hung in chronological order. He ventured to assert that the King's College Classes now provided all that was necessary for the training of the young architect.

The vote of thanks was seconded by the Master of the Carpenters' Company (Mr. Jacobs), and carried by acclamation, and was briefly acknowledged by Mr. Lucas.

SHADOWS IN PERSPECTIVE.—VI.

WE are now going to study the construction of shadows cast by rays of light coming from before the observer. It is evident that before putting in the shadows of a drawing we have to consider the best effect that can be produced by

Fig. 12. Source of light before the observer.

their means. We have, as we have said before, three positions of the source of light to choose from: that sending its rays parallel to the plane of the picture, and which we have already studied; the rays coming from before the observer, and, again, those coming from behind the observer. If we have a drawing disposed as in Fig. 12, which we have kept very simple, in order to better explain the construction of the shadows, we will at once notice that shadows found according to the first system would make no effect. If coming from the left hand there would be very little shadow, and if from the right hand the shadow thrown by the building would cover the whole drawing. In this and such cases we will see that if we suppose the source of light to be situated before the observer we shall obtain effective shadows. We will, therefore, suppose the sun to be before the observer, and at any given distance above the horizon. We shall understand at once that the rays of light (unlike those coming parallel to the picture plane) are no longer parallel to each other, but will follow the same laws of perspective as used for the drawing.

Let us first decide the position of the sun, at any distance above the horizon, say at S, Fig. 13. The rays of light striking the angles of the wall A B are, of course, not parallel to each other, but diverge in proportion to the distance of these points from each other. We have in Fig. 13 a surface of wall, A B, at right angles to another wall, X x, and we wish to find the shadow cast by A, B against the ground and wall planes. We must find the projection of S on the horizontal line at s. For the shadow of A a, it is evident that the intersection of the lines from S and s passing through A a will give us the shadow a, a 1 of A a. S, a 1, s is a plane containing the rays of light and passing through A a. Another plane from S s passing through B b would give us the shadow of B b against the ground at b, b 2, the shadow of the crest of the wall, A B, would fall on the ground from a 1 to b 2. But this plane is intersected by the wall X x at B b, the shadow will, therefore, follow the ground as far as the wall at b 1, and from thence be cast against the plane of the wall. But this shadow must itself be in the plane of the wall; we have, therefore, to turn the plane S, b 2, s on its axis, B b, until it becomes one plane with the wall X x. The plane of X x contains the vanishing point, v, the projection of v to V on the horizontal line from S will therefore be the new position of s S, and the shadow line, B, b 1, will be the line drawn from point V, passing through B, and

meeting the ground at b 1 on the horizontal line from a 1. We see, therefore, that the shadow thrown against the wall should be in the plane of the wall, and on the line from point V. If the drawing was put into perspective with two points, one at v and the other to the right, the point V would naturally be on a line drawn from S to the vanishing point to the right.

We will now find the ordinary shadows of Fig. 12, which is in parallel perspective. The

Fig. 13

position of the sun we will suppose to be at S, and its projection on the horizontal line at s, and the projection of the vanishing point v will be at V on the horizontal line from S. To find the shadow of A a against the ground, we must draw from s a line passing through a as far as a 1, and another line from the source of light, S, through A, meeting a, a 1 at a 1. From B a line from S will give us b, the shadow of B; the horizontal from b will be the shadow of the crest of the wall, and b, a 1 that of B A. The shadow of the crest of the wall A O will be the horizontal line drawn from a 1, meeting the wall plane of the building

at o 3, and from thence on the wall to O. o 3, O is the line drawn in the direction V O from the point V. The shadows of the angles of the open doorway are found in a similar manner. The lines from S s passing through the outer angle C c of the doorway meet at c 1, making C, c 1 the shadow of C c. From c 1 we draw the horizontal line c 1 and 3. The shadow of the lintel at D being thrown against the side of the doorway must be drawn from the point V as far as D D, but from D the shadow-line must be drawn from point S, meeting at d 1, the vertical d 2, d 1 drawn from d 2, where the shadow-line drawn from v through d meets the walls. From point d 1 the shadow of D d is against the wall, and must therefore be drawn from the point V, and meets the ground at point d 3. The proof that the construction is correct is that the lines on the ground and wall planes should meet at the same point, as at d 3 and o 3. We therefore see that the point V is not always necessary for the construction of the shadows, for having obtained the points d 3 and o 3 by means of the horizontal lines from c 1 and a 1, we have only to join the different points on the wall plane in order to have the shadows. The use of the point V is, however, always advisable. The shadow of the projecting eaves is found by means of the lines drawn from S and V, passing through G and g respectively, and meeting at g 1; the line from g 1 from the vanishing point completes the shadow. The projecting window-sill intersects the shadow-line O, o 3, and also casts a shadow of its own. The lines from S and V passing through M and N respectively meet at n 1, and give us N, n 1, m the shadow of M N; the line drawn from m to the vanishing point, and meeting s, o 3 at o 2 given us m, o 2, the shadow of the lighted portion of the sill M S. A horizontal line from s beneath the sill will give the point and shadow S (drawn to the point V) on the advanced plane of the sill. The window will be entirely in shadows as seen by the constructional lines X x, x 1. The shadow of the log of wood may be left for the student to construct; the shadow of the crest of the wall will fall on the raised plane of the log at o 1. The pole F f, although appearing well above the wall, will, however, owing to its distance therefrom, cast only the short shadow at f 1. The brick on the wall above the doorway at P casts a lengthened shadow, owing to the slight distance separating the points S and V. It is easily understood that the further the point S is moved to the left the shorter will be the shadow of P, and, again, the greater the elevation of point S the shorter the shadows on the ground will be, and inversely. The position of this point, therefore, should be carefully studied before commencing the shadows of a drawing, in order to obtain the best effect possible. The student would do well to put the Fig. 12 into ordinary perspective by means of a second vanishing point to the right, taking care, however, to notice that the point V will be in that case on the line drawn from S to the second vanishing point.

ARTHUR VYE PARMINTER.

CHIPS.

The annual meeting of the Ruskin Society of London is to be held this (Friday) evening, in the Governor's Room of the Charterhouse, by permission of the master, when Canon Elwyn will point out and describe the chief features of interest in the ancient buildings of that foundation. The programme of this "Society of the Rose" for the coming winter includes some very interesting lectures, which will be delivered at the London Institution.

A subscription portrait in oil of Sir James Maitland, Bart., of Sauchie and Barnton, convener of the county of Stirling, was presented to him on Friday. The portrait, which is a full-length one, has been executed by Sir George Reid, P.R.S.A., and will hang in the council chamber at the County Buildings of Stirling.

Messrs. Maxwell and Tuke, of Manchester, have been selected as the engineers to the Douglas Head Marine Drive.

The memorial-stone of a new Congregational chapel, at Newton Heath, Manchester, was laid on Saturday. The building is situated off Thorpe-road, Newton Heath, with a frontage to Jessie-street. It will be mainly a brick structure, Runcorn sandstone in conjunction with Accrington red bricks being somewhat freely used. Accommodation will be provided for about 330, and the cost will be £1,900. The architect is Mr. S. Fell, of Manchester, and the builders are Messrs. Moore and Son, Eccles.

LLANELLY TOWN-HALL COMPETITION.

(DESCRIPTIONS of the premiated design and that actually adopted will be found on p. 545.)

SELECTED DESIGN FOR POPLAR PUBLIC LIBRARY.

THIS building, illustrated by plans, elevations, and sections, is an example of a type of plan differing in some respects from that generally adopted. The site selected has a narrow frontage to the main road, and a large piece of cheap land at the back. The commissioners wished, as we understand, for a building which could be attended to by a very small staff, and decided that all the departments should be on one floor, and commanded from the lending library. Everyone entering or leaving the building will be seen by the attendants at the counter, and each room will be under the observation of the staff at short intervals—when books are being handed out in the reference room, or fetched from the bookcases adjoining the newsroom. Top-lighting is avoided in the rooms for readers, ordinary windows in the walls and windows in a sort of clerestory being preferred. The newsroom is arranged for 100 persons, the size being about 40ft. by 24ft.; the rear portion of the room will have tables for readers of magazines, &c. The entrance to the newsroom is in full view from the entrance-hall. The reference room is about 52ft. by 30ft., giving seats for 100 readers, each being allowed 2ft. of table. The room will be very quiet, as it is out of the reach of the noise of street traffic and of the lending library. The hall will be used for university extension lectures and similar purposes; it will seat about 200 persons. The architects, Messrs. Clarkson, of Great Ormond-street, and 146, High-street, Poplar, have prepared for 40,000 volumes in all. Books are now being collected by the librarian, Mr. Henry Rowbutt, at No. 149, East India Dock-road; a thousand volumes have been presented by Mr. J. Passmore Edwards, the proprietor of the BUILDING NEWS, the *Echo*, and other journals, and we believe further donations will be welcome. The librarian's residence in the new building will be placed next the road in upper floors, and will consist of two rooms, kitchen, and offices on the one pair, and four bedrooms on the two pair story, the entrance doorway being in the next portion of the front next East India Dock-road. That front will be in Portland stone. The building will be wired for the electric light, as that light will be available shortly for the public buildings at Poplar; the heating to be low-pressure hot-water, with boiler in the basement and radiators in the rooms.

WOOD VAULTING UNDER RINGERS' ROOM, WINCHESTER CATHEDRAL.

(See description and further sketches on pages 520, 521.)

HASELEY HALL, WARWICKSHIRE.

SITUATED four miles to the north of the county town, Haseley is a primitive little rural village in the heart of Warwickshire, not without historical associations, and with a population of about a hundred and fifty souls. The Haseley Hall estate, which lies between the estates of Wroxall Abbey and Haseley Manor, and formerly belonged to the late Sir Edward Antrobus, Bart., who was lord of the manor of Haseley, was purchased by Sir James Sawyer, M.D., about two years ago. This beautiful demesne, richly wooded and with picturesquely undulating pastures, adjoins the high road from Warwick to Birmingham, the road forming the western boundary for about a mile. On its eastern side the estate is skirted by a goodly stream, the Inchebrook, which supplies the borough of Warwick with water, and passes its waters into Shakespeare's Avon as a tributary of the Sowe. The extensive alterations and additions have been carried out by Mr. T. Rowbotham, builder, Coventry-road, Birmingham, from the designs, and under the superintendence of, Messrs. Wood and Kendrick, architects, West Bromwich.

RESIDENCE OF D. R. THOMSON, Q.C., LVII. QUEEN'S PARK, TORONTO, CANADA.

THIS house is situated in what might be called "Architects'-row," the five or six residences adjoining being designed by as many different men. The lower portion of the building is of dark brown stone in rock-faced random work, and the upper portion of brick faced with red pressed brick of dark colour. The front is timber-framed, with brick filling in, and the gables of dark red tiles. The exterior woodwork is painted in shades of brown to harmonise with the colour of the stone. The interior is finished in hardwood throughout, the drawing-room in hazel or sweet gum, the hall and dining-room in quartered oak, the library in cherry, and the first and second floors in black ash. The basement is fitted up with a laundry, and contains store-rooms, fuel and boiler rooms. An additional bath-room is provided on the second floor. Every room and hall in the house is heated with hot water, the radiators being indicated by an X and the coils by dotted lines. The boiler is a cast-iron sectional one of the "Daisy" pattern, made in Montreal, being a powerful and economical heater, burning anthracite coal. The following items of cost may be of interest to English readers:—Mason, brick, and plastering, 6,938-80dols.; carpenter and joiner, 6,841-53dols.; tinsmith, 91dols.; slater and tiler, 470dols.; pavement, 132-58dols.; carving at entrance, 20dols.; plumbing and heating, 2,205-29dols.; grates and tiles, 320 50dols.; bells, 47-75dols.; terracotta, 194dols.; painting and glazing, 1,386-47dols.; mantels, 276-78dols.; grading, 28dols.; total, 18,952-70dols. Messrs. Langley and Burke, of Toronto, are the architects.

The theatre at Castleford, Yorks, is being reconstructed from plans by Mr. A. Hartley, architect, of that town, in accordance with the requirements of the County Council for the West Riding. Stone staircases are being provided, also a fireproof proscenium wall and new exits. Messrs. Wilson and Son are the contractors.

The installation of the electric light at Ardrossan Harbour has been completed. It consists of seventeen arc lamps of 3,000 candle-power each, distributed around the harbour and in the coal elevators and Caledonian Railway Station. The dynamo and engine are fixed in the hydraulic engine-house. The work has been carried out by Messrs. Mayor and Coulson, of Glasgow, under the superintendence of Messrs. Strain, Robertson, and Thomson, the Harbour Company's engineers.

On Wednesday last the Bishop of Shrewsbury reopened St. James's Church, Horsley Fields, which has undergone renovation. The work carried out includes the removal of the north and south galleries, and the stone pulpit has been taken down and placed at the south-west angle of the chancel. The enlarged organ has been erected in the bay of the north aisle and the exterior of the building restored. The work has been carried out by Messrs. G. and T. Perry, Wolverhampton, and the alterations to the organ by Messrs. Nicholson and Lord, Walsall. Mr. T. H. Fleeming, Wolverhampton, was the architect. The cost has been £500.

ARCHÆOLOGICAL.

ROCHESTER.—The recent discovery of the foundations of the old east gate of Rochester was discussed at the meeting of the Rochester city council on Wednesday evening, and it was decided to instruct the city surveyor to prepare plans for a subway, the construction of which would enable visitors and others interested to inspect the old tower. The town clerk advised that the city wall was the property of the corporation, and he pointed out that where owners of property had built up to the wall in other parts of the city they had been compelled to pay rent. On the other hand, the clerk to the governors of the Free School holds that the portion of the wall in question belongs to the governors, who have never paid any rent. It was finally decided that the wall should not be pulled down without the consent of the corporation. At the same meeting it was resolved that some important repairs should be carried out in the castle, and a suggestion was made that money should be borrowed to roof it in—the roof not to be visible from the exterior—and that other steps should be taken to insure the preservation of the ruins.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

MANCHESTER SOCIETY OF ARCHITECTS.—The first sessional meeting of the Manchester Society of Architects was held on Tuesday week, the president, Mr. Salomons, in the chair. Mr. F. W. Bedford, A.R.I.B.A., read a paper on "Some Account of the Arts in Sicily," which was illustrated by lantern views and sketches. A large collection was exhibited of drawings made during a year's tour in Italy by the lecturer as the Owen Jones travelling student of the R.I.B.A.

CHIPS.

It is the intention of the directors of the Great Western Railway Company to spend £20,000 in enlarging and improving the accommodation at their station in Bath.

The old colours of the First Battalion of the Buffs were handed over to the Dean and Chapter of Canterbury on Monday and deposited in the Warriors' Chapel in the Cathedral. They have been fitted up near the Buffs' Memorial Window.

The township commissioners of Bray, Co. Dublin, are carrying out extensive improvements to the harbour, including the extension of the north and south piers. Messrs. Comber and Strype are the engineers.

On Saturday Lady Margaret Cecil laid the foundation-stone of a new parish mission room in Warington-road, Prescot. The building is being erected at a cost of £1,800. The plans have been prepared by Messrs. Wolfall and Eccles, architects, Castle-street, Liverpool, and Mr. Peter Taylor, of Prescot, is the contractor.

The Corporation of Dublin have decided to promote a Bill in the next Session of Parliament for amending, enlarging, and defining the powers of the Corporation as to borrowing and application of money borrowed, and for confirming and providing for the expenditure of money on the Dublin Main Drainage and on the extension and improvement of the Dublin Corporation Water Works. One of the objects of the measure will be to raise £250,000 for providing artisans' dwellings.

A new bridge has just been erected over the Scottish River Avon, near Blackstone Junction. The bridge has been constructed at the joint expense of the Linlithgowshire and Stirlingshire authorities. It has a clear span of 50ft. and consists of two main lattice girders.

Owing to the serious depression in the South Staffordshire iron trade, the workmen employed by Messrs. Cochrane and Co., bridge and girder manufacturers, Woodside, near Dudley, have met their employers, and, in order to assist them to compete in the iron markets, have consented to submit to a reduction of 5 per cent. in wages all round. The workmen number nearly 1,000.

The new public park at Portobello was opened on Saturday. The park, which consists of a field of about sixteen acres, is situated on the north side of the North British Railway, between Hope's-lane and Joppa.

The employees of Mr. James Evans, builder, of Norwich and South Walsham, were entertained at supper last week by Messrs. Charles Havers and Son, ironmongers, in celebration of the roof-raising of their new premises, which are in course of erection from plans prepared by Mr. A. C. Havers, architect, Bank Plain, Norwich.

WAYSIDE NOTES.

TWO new literary works of interest to the architectural profession are about to be published. One is an early effort of Mr. Ruskin to reduce to something like order the ill-defined principles of architectural design, and the other is the promised selection of essays that Mr. Murray has been occupied in printing. The former work will certainly deserve attention, and may perchance contain many practical hints on design for which we look in vain in much of the letterpress of Mr. Ruskin's beautiful book on matters architectural. It may be that we shall not feel any compunction to place implicit faith in the correctness of the deductions made by the author, seeing that the work was produced when he had scarcely arrived at man's estate. But the early impressions of great men have the stamp of genius, and are always interesting. In later—later as to date of production—works, Mr. Ruskin has said much with regard to rules of composition, but the information is of a desultory kind, and generally lost in a vast deluge of beautiful language which, however interesting or instructive, is not, strictly speaking, practical and workaday. In a certain sense, too, Mr. Ruskin has revoked any of his earlier views on the principles of design. I think that it is in a late edition of the "Seven Lamps of Architecture" that there is a footnote to the effect that laws and principles of composition are as nothing compared with the correctness of the workers who have produced the actual building.

There should be somewhat of a thrill in the architectural world at the announcement of the near publication of the essays *re* "Architecture: an Art or Profession." I note that the "Art" comes first in this case, and, like a shadow, would, if we did not already know things, foretell events. I fancy that on the publication of this work all the fat will soon be in the fire, and things will be lively at Conduit-street. Another attack will be made on No. 9, and the Institute particularly harried. If that body frankly avows itself to be an *Institute of Architects*, and neither by title nor special wish an *Institute of Architecture*, its position will remain, as heretofore, impregnable. So long as bread-and-cheese has to be earned in the capacity of an architect, there is ample right to uphold the existence of an Institute of Architects. It may be that the writers of essays on high architecture are above the common necessities of life, and live in an atmosphere of intellectuality. They therefore would fail, naturally enough, to recognise the claims of anything but an Institute of Architecture. In which event the wisest and most consistent course would be to found such an institute which should be kept pure and uncontaminated from contact with common architects and commonplace architecture. And I don't say but what such an institute might not find a great many things in its way that would worthily occupy its attention.

I have a copy of the *Victoria Daily Colonist* for Sept. 13, and therein find a perspective view of "The New Christ Church Cathedral, Victoria, B.C.," Messrs. Evers and Keith, architects. I fear that I have not taken sufficient note of the various illustrations which you have given of this competition, and do not call to mind the nature of the accepted design; but the illustration in the *Victoria Daily Colonist* makes the building, so far as regards its general grouping of features and outline, remarkably commonplace. Of its detail one cannot judge by such a drawing; but I should imagine that it would require a lot of good work to compensate for the apparent lack of originality and ingenuity in its composition. But we must not criticise from data so insufficient as that afforded by a slight and not over-artistic sketch. As to the realisation of the design, I read that the plans have been approved by the general committee, and that tenders will be now invited, while the work of construction will be undertaken in sections. The following will be of interest—uncommon interest, possibly—to the second and third premiated competitors:—"It was resolved that these plans should be finally adopted, and the bonus paid to the successful firm. There was some discussion about the payment of the second and third bonuses, which were on plans prepared in England. It appears that there are certain conditions in the terms of the contest which the competitors failed to comply with. The matter

was referred back to the plans committee, with power to act." It is most probable—unless any have subscribed to a local journal for a season—that this is the first intimation of this meeting of the committee that English competitors will have had, and I should rather like to know how it will strike premiated competitors Nos. 2 and 3.

The Dean of St. Paul's having been approached with reference to the interment of the late Mr. Woolner, R.A., in the cathedral, although expressing personal sympathy with the application, thinks that every perforation of the bed of concrete upon which the cathedral stands involves an appreciable injury to its foundations, and is, therefore, averse to interments within the building as far as possible. One feels strong sympathy with the Dean's views. Some day, perhaps, interments within buildings will be discontinued, and remembered only as one of other barbarisms of olden times. Certainly, interments that interfere with the stability of a fine national monument or cathedral should not be undertaken. We know that the Dean of St. Paul's has every reason to suppose that his views are founded on fact. If St. Paul's floats on a sort of raft or vast tray, it will not do to make any hole in the tray, or otherwise the floating power will be reduced. It is an old tale, this, about St. Paul's, and no doubt worthy of every credence. At any rate, we had best be on the safe side, and not have the Cathedral tumbling about our ears.

Readers will have noticed Mr. Loftus Brock's communication to the *Times* respecting an antiquarian discovery at Rochester. During the rebuilding of the old Free School at that town, now in progress, efforts have been made to trace the form of the old east gate of the city, which formerly stood close to the site of the school, and some excavations made have revealed the form of a huge circular tower, the existence of which had been previously known to a few investigators. Mr. Loftus Brock thinks that it is one of two towers which originally flanked a central gateway, the base of the second tower being supposed to remain beneath the present roadway on the opposite side. The work is found to stand on the ruined wall of a still earlier tower of larger size, the masonry of which agrees with the Norman walling of the castle, and evidence is thus, for the first time, obtained of the existence of masonry defences to the city anterior to 1225. I am glad to hear that the Corporation of Rochester have decided to protect the remains, and render them accessible to those interested.

With the Tower Bridge approaching completion, the river-side residents and others lower down the Thames are naturally thinking that they too should have some means of communication. Another Tower Bridge being out of the question, the County Council Bridges Committee have prepared a scheme for a ferry at Rotherhithe, at a cost of £418,000 the provision to consist of three steamers, each of which will make a round journey in 20 minutes, and capable of carrying 14 vehicles and an "unlimited" number of passengers, whatever that may mean. This scheme of the Bridges Committee received much criticism in council, and has been referred back for further consideration. To us the idea seems useful, and there should be quite sufficient traffic to make the undertaking worth realisation. Tunnels are costly, and apparently difficult things to construct, and more bridges must not be placed across the Thames below the Tower Bridge until, indeed, London has developed into a totally different city.

GOTH.

Engineering Notes.

POLQUHOLICH, N.B.—A new suspension foot-bridge across the Dee at Polquhlich, about two miles above Ballater, was opened on Saturday by the Duchess of Albany. The bridge is the gift of Mr. Alexander Gordon, London, a native of the district, and is of the stiffened lattice girder type. It is 195ft. in length, with a breadth of roadway of 4ft. The height of the roadway above the water is 12ft. The foundations are all of concrete, and go down below the river bed. Those for the towers rise 9ft. above water level to keep the iron superstructure clear of the river during flood. The lattice towers are of steel,

and 23ft. in height. Two 5in. steel iron cables, with a breaking strain of 70 tons, carry the bridge. The roadway is stiffened by two side lattice girders, standing 3ft. 9in. high, while the flooring is covered with wrought-iron chequered plates. Messrs. Abernethy, Aberdeen, were the designers and contractors, and the bridge cost about £500.

THE NEW WIRRAL RAILWAY.—The first sod of the new railway across the Wirral peninsula from Birkenhead to the Dee Bridge will be cut by Mr. Gladstone on Friday in next week. The directors of the Manchester, Sheffield, and Lincolnshire Railway, who are constructing the line, seek to obtain a connection between their system beyond the Dee Bridge and the Birkenhead docks for mineral and goods traffic. For that purpose a main line will be constructed from the Dee Bridge, and will join the Seacombe, Hoylake, and Deeside Railway at a point near the Birkenhead Docks Station. The picturesque but inaccessible district of Wirral will be opened out by the construction of the new line. It is intended to place six stations between Birkenhead and the Dee Bridge, the names of which will be Bidston, Upton, Prenton (or Landican), Heswall, Neston, and Burton.

PROJECTED KETTERING AND RUGBY RAILWAY.—A meeting of the Traders' Association was held on Thursday in last week to consider the advisability of agitating for a second line of railway to the town. A sub-committee had, with Mr. Thos. Hennell, engineer, of London, made a personal survey of the district, and they recommended that there should be a railway from Kettering to Rugby *via* Rothwell, Harrington, Kilmarnock, Naseby, Welford, and joining the L. and N. W. Railway at Stanford; that the railway should have an independent station on the east side of Kettering; and that a guarantee fund of £2,000 be formed to cover the expenses of promoting a Bill for this route in the next session of Parliament. The engineer stated that the line would be about 19 miles in length, and he estimated the cost at about £300,000. The committee's recommendations were adopted.

PROPOSED NEW RAILWAY FROM MANCHESTER TO GLASGOW, VIA NEWCASTLE.—Influential meetings have been held this week in Newcastle and Sunderland to consider the details of a proposed new railway, probably, although the parentage is not yet avowed, an offspring of the Manchester, Sheffield, and Lincolnshire system. According to the plans as explained by Mr. Baker, joint engineer with Mr. Cooper to the promoters, the proposed line will run from Manchester to Newcastle, and on to Glasgow, and it is expected that there will be a saving of about forty-eight miles between Newcastle and Glasgow, and from twenty to twenty-five miles between Newcastle and Sunderland and Manchester. The new line will pass through Darlington, and then through the populous mining district of Houghton-le-Spring, thence to Sunderland. The Wear would be bridged at Deptford, and the line would run *via* Workington to Newcastle, a saving of about one mile and a half, as compared with the present North-Eastern route. From Newcastle, a rich agricultural portion of Northumberland would be served, and Hawick, on the borders of Scotland, on the way to Glasgow. Two bridges over the Tyne are spoken of—one at Hebburn, in order to obtain direct access to the Albert Edward Docks, and the other for the main line higher up the river. It is also proposed that there shall be a loop-line coming through Stockton, Hartlepool, Seaham Harbour, and on to Sunderland. If access can be gained to the docks at Sunderland, a greatly developed business with Yorkshire, Lancashire, and the Midlands would probably result. The project, which is estimated to cost ten millions, will undoubtedly be strongly opposed by the North-Eastern Company, on whose preserves the promoters seek to poach. Mr. Cooper, the joint engineer, is also the engineer to the east-to-west route between Manchester and Sutton, of which the first section is now being made.

In the City of London Court, on Friday, William Barnes, a youth, obtained £175, for injuries sustained in consequence of a defect in the machinery of J. Tyler and Sons, Limited, brassfounders, 2, Newgate-street, by whom he was employed. Both of his arms were broken, one of his legs was dislocated, and it was stated that he would probably be disabled for life. The defence was that the plaintiff had no right to touch the machinery.

LLANELLY TOWN-HALL COMPETITION.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

WE publish both the first and second premiated designs in this competition, awarded in accordance with the report of the referee, Mr. Chas. Barry, F.R.I.B.A. The plans and elevations bear witness to the justice of his award. The second design has been selected for execution by the town council, and Mr. William Griffiths, F.S.I., of Llanelly, is the architect appointed for the work.

Selected Design.—Mr. Griffiths' building is to be erected in the park, and is a free treatment of the Classic style, adapted to the use of the local stone, and aims at a dignified and substantial appearance. The main entrance faces Salamanca-road, and an entrance is also provided on the south side specially for officials connected with the court. The external walls are to be of dressed rock-work of local stone, the dressings and carvings to be of Box Ground. The floors to be fireproof on the Dennett's system, the entrance-hall, portico, and corridors to be laid with marble mosaic, the other floors to be of wood blocks. The ground floor is for the use of the court and rooms in connection therewith. The collectors' department is also placed on this floor, as being most used by the public. The court or town-hall is placed in the centre, being easily accessible from corridors 6ft. wide, and provides, together with the gallery, public accommodation for 300 in addition to the court officials. The hall is lighted by five large windows in the west end and three large lights in the ceiling, with small windows running below the frieze, and, being near the ceiling, can be utilised for ventilation. To the left, and in direct communication with the bench, is the judge's retiring room, and to the right the jury retiring room. The dock is connected to the cells by a private flight of stone steps. The barristers' room, witness room, and solicitors' room are convenient and easy of access to the court. The registrar's offices, with book room, are placed on the north side and in close proximity to the high bailiff's office. Extensive lavatory accommodation is provided both for the officials of the court and the public. The first floor is arranged for the various offices in connection with the Local Board—viz., the surveyor's department (three rooms), the town clerk (three rooms), with a book room for daily use (a large strong room being provided in the basement), medical officer's and inspector's room. The council chamber, 38ft. 3in. by 21ft. 3in. by 16ft. 6in. high, lighted by three large arched windows (the middle one gives access to a balcony), a sub-committee room and waiting-room for deputations, lavatories, &c. The corridors are lighted by top lights. In the basement are situated the photographer's room, strong room, and caretaker's apartments, with direct access to the boiler-room, so as to insure proper attendance to the heating apparatus. The cells and police room are approached by a private entrance on the west side. It is proposed to heat the building by means of radiators, and the ventilation on the Tobin's system, with outlets for vitiated air connected with flues to the main ventilating trunk, and carried along the roof and discharging in the small clock tower.

First Premiated Design.—Messrs. F. W. Simon and Tweedie, architects, of Edinburgh, are the authors of the design placed first. Their report says:—"A central entrance gives access to a spacious vestibule or entrance-hall, from which diverge to the right and left two main corridors, giving access right round the town-hall. The corridor and apartments to the left are devoted to the court business, and those to the right to municipal business. The two departments are thus kept quite distinct, and can be cut off by means of swing doors and glazed screens when the town-hall is used for court purposes only. The main staircase leading to the first floor is centrally placed immediately facing the entrance. On the first floor, again, the departments are kept distinct, and the various apartments are grouped together. The council chamber and the three clerks' rooms and waiting-room occupy the main front. The county court accommodation occupies the left-hand corridor, and the surveyor the right hand. The town-hall is so arranged that it can be used for general meetings, when the dock and the whole of the seating will be removed and deposited in a store in the basement under the hall. From the dock

a staircase leads to an underground passage communicating with the two waiting-rooms or cells for prisoners. These are on the ground level, and can also be approached from the corridor at the back of the hall, and form the yard separating the main building from the caretaker's house. The prisoners' van can be driven into this yard, and prisoners placed in the cells to await their turn in the dock. It was thought desirable to place the caretaker's house on the ground-floor level, forming an annexe at the rear, and grouping with the main building. Thus the inconvenience of placing the caretaker in some remote corner of the roof is avoided, and he has easy access all over the building externally and internally, and full command of the cells and basement. Lavatories and w.c.'s are placed throughout the building in convenient places for private and public use. The design is based on the English Renaissance, which lends itself so well to a picturesque and effective treatment. The buildings externally would be faced throughout with stone, with freestone dressings, the roofs being covered with slates, with ornamental terracotta ridges. The entrance-hall is treated with columns and panelled and decorated ceiling, the staircase being richly balustraded. The corridors and offices will be of simpler design, a richer treatment being reserved for the council-chamber, with high dado, and coffered and panelled ceilings. The town-hall will be panelled to a height of 9ft., and above that be divided into large panels by pilasters with moulded capitals and rich wall-head cornice, from which will rise the elliptical ceiling, richly panelled, and divided by deep moulded ribs, with pendants at their intersection. The construction of the floors will be of steel joistings embedded in concrete, and the roof construction of town-hall will also be of steel. Open fireplaces are provided in all the offices, but the town-hall and entrance-hall will be heated with hot water. Special attention will be paid to the ventilation of the town-hall. A large ventilator is being placed in the centre of the roof with a Bunsen draught inducer communicating with a trunk carrier along the top of the ceiling, with foul-air openings into same at various points. Inlets will be provided for admitting fresh air over hot-water coils. We have carefully gone into the cost of the buildings, and estimate that they can be executed in a first-class manner for a sum of £10,000. With reference to the request to state architects' fees, we take it that the board desire to be assured that the architects' usual fees—namely, 5 per cent. commission on the cost of the building—will be held to cover all charges for professional services from commencement to completion, and that the board only desire to decide the competition on the merits of the plans sent in."

OBITUARY.

WE regret to announce the death of Mr. James Fowler, F.R.I.B.A., J.P., of Louth, the well-known church architect, which took place on Monday. Mr. Fowler had recently recovered from a long illness, but succumbed to a chill taken when on a visit to Grimsby on Thursday last week. Mr. Fowler was born in 1829, and was a pupil of the late J. Potter. He was from 1871 to 1886 diocesan surveyor for Lincoln, and erected and restored a large number of churches, his new works including St. Mary's, Newington, S.E. (see illustration in the BUILDING NEWS for Sept. 24, 1875), Holy Trinity, Wanstead (illustrated by us May 23, 1890), St. Swithin's, Lincoln (a building having a fine spire), St. Andrew's, in the same city, St. Mary's (Lonsdale memorial), Lichfield, and St. Michael's, Louth. Among his restorations may be named St. James's, Louth, Heckington, and Bolingbroke churches, the old Bishop's Palace at Lincoln, Browne's Hospital, Stamford, and Dingley Hall, Northants. He also built the Grammar School and Savings Bank at Louth, Market Rasen School, and built and enlarged the halls at Morton, Langton, and Dalby. Since 1864 he had been a Fellow of the Royal Institute of British Architects, and served on its council 1886-1890. Until this autumn, when ill-health prevented him joining the party at Taunton, he took an active share in the excursions of the Architectural Association, of which body he had been a member for the past eighteen years. Among his published works are "The Ancient Monastic, Ecclesiastic, and Domestic Edifices of Lincolnshire," and "The Churches of the Middle Ages." In the

town of Louth Mr. Fowler was a prominent and highly-respected figure. He filled many public offices in the borough, and five times served as mayor, and on one occasion, in 1886, presented to the corporation a gold mace. He was also warden of the Grammar School, a magistrate and alderman for the borough, chairman of the Louth Court of Sewers, and president of the local Conservative Association. We gave a portrait and biography of Mr. Fowler in our issue of July 4, 1890.

Mr. Thomas Woolner, R.A., the well-known sculptor, and one of the few survivors of the pre-Raphaelite brotherhood, died very suddenly on Friday evening, aged 66 years. Born at Hadleigh, Suffolk, he became, when in his nineteenth year, a pupil of William Behnes, the painter and sculptor, whom he soon excelled both as a draughtsman and an executant. His first exhibit at the Academy was "Queen Eleanor sucking the Poison from Prince Edward"—a work which attracted much attention when shown in 1843—and other imaginative works followed in successive years. In 1850 he joined with Millais, Dante Gabriel Rossetti, and Holman Hunt in originating the short-lived periodical, *The Germ*, to which he contributed several poems, which have frequently been reprinted in later years. The two years 1862 to 1864 were spent at Melbourne, where, among other works, he executed a colossal bronze statue of Captain Cook, now a feature of Hyde Park, Sydney, and the bust of Edward Wilson, of the *Melbourne Argus*, purchased by subscription, and placed in the Public Library of the latter city. After his return, Woolner almost abandoned his idealisations, and confined himself to the more remunerative work of executing statues of public men, and his commissions comprised nearly all the most eminent men of his time. His life-size statues include Lord Macaulay, Sir Bartle Frere, Dr. Whewell, for Cambridge; Lord Lawrence, for Calcutta; Lord Palmerston, for Palace-yard; Lord Frederick Cavendish (a recumbent effigy), for Carmel Priory Church; Bishop Fraser (in bronze), for Manchester; and Lord Chief Justice Whiteside, for Dublin. Among his busts are those of Thomas Carlyle, Cardinal Newman, Charles Darwin, Rajah Brooke, Professor Sedgwick, Sir W. Hooker, Richard Cobden, Sir Thomas Elder, Charles Dickens, Canon Kingsley, W. E. Gladstone, and Lord Tennyson. His most conspicuous failure was the George Dawson statue, for Birmingham, which was removed from its original position; but generally his works were characterised by conscientiousness and thoroughness. He was elected an Associate of the Academy in 1871 and an Academician in 1874, and from 1877 to 1879 he held the Professorship of Sculpture in that institution. His diploma work, executed in 1876, was a figure of Lady Godiva about to mount her horse. He leaves a widow and five children.

The death of Dr. Edward Bickersteth, who only resigned the deanery of Lichfield ten days before his decease, should not be suffered to pass unnoticed in our pages, for the construction and successful completion of the restoration of the west front of his cathedral, effected at a cost of £41,000, under the supervision of Mr. J. Oldrid Scott, were entirely due to his persistent and untiring efforts. Only three weeks since a statue of Dr. Bickersteth, executed some years since by Mr. Ingram, of London, was placed, by order of the Chapter, in the niche that had been left vacant for its reception in the arcade above the west portals of Lichfield Cathedral.

Mr. Charles Macdonald, Froghall Granite Works, Aberdeen, died at his residence on Saturday night. He was an extensive exporter of polished granite to various parts of the world, especially to the colonies. Some time ago Mr. Macdonald, who was much interested in benevolent and educational work, made a gift of a convalescent home, which is maintained at Culter, in connection with the Aberdeen Sick Children's Hospital.

Mr. William Thompson, who had been twice Mayor of Lynn, senior partner in the firm of Thompson, Patrick, and Woodward, timber merchants, died at Glaisdale, Yorkshire, on Tuesday evening, aged 61.

Messrs. E. B. Martin and W. Fiddian have been appointed engineers to the recently constituted board of drainage for the Upper Stour.

COMPETITIONS.

AMBLESIDE.—In the competition for Assembly Rooms at Ambleside, the designs of Mr. Robert Walker, architect, of Windermere, have been accepted by the committee.

NORWICH SCHOOL BOARD.—The above board, at their meeting on Friday last, the 7th inst., awarded the three premiums in the Avenue-road School competition to the authors of plans as follows: First, Mr. C. J. Brown, architect, Norwich (surveyor to the school board), selected to carry out the works; second, £50, Messrs. George J. Skipper, F.R.I.B.A., and F. W. Skipper, architects, Norwich; third, £25, to Mr. W. Landless, architect, Leeds. There were 32 sets of plans submitted.

PADDINGTON.—A very considerable addition is to be made to St. Mary's Hospital, Cambridge-place, on an extensive site in Praed-street, and a limited competition is being held, the following architects having prepared plans—viz., Messrs. H. H. Collins, Henry L. Florence, Stephen Salter, Searle and Hayes, and Keith D. Young. The new buildings will form the Clarence memorial wing. No award has been made as yet, and it is not decided at present who the referee will be. The site is already cleared for the most part, and the buildings when erected will have a very important frontage.

SHEPTON MALLET, SOMERSET.—We understand that in this competition for local board offices and technical school the authors of the selected design under motto "Mid-Somerset" were Messrs. George J. Skipper, F.R.I.B.A., and F. W. Skipper, architects, Norwich. The design placed second, under motto "Merlin," was by Mr. Silcox, of Bath.

STOCKTON-ON-TEES.—At the last meeting of the Stockton School Board, a report by Mr. E. R. Robson, F.S.A., architect to the Education Department, as assessor on the designs submitted in competition for the higher-grade school, was read. Mr. Robson had placed first the designs of Mr. Bottomley, architect, of Middlesbrough, whose motto was "Respect Finem"; Messrs. Clark and Moscrop, Darlington ("Ad Rem"), next; and Mr. Richardson, of Stockton ("Martin Chuzzlewit"), third. The report was adopted.

WALSALL PUBLIC BATHS.—At Thursday's meeting of the Walsall Town Council a resolution of the baths sub-committee was brought forward that the premiums for the three best sets of plans for the baths be awarded—the first to the author of the design bearing the motto "Expert," the second to the author of the design bearing the motto "Mermaid," and the third to the author of the design bearing the motto "Health." The first premiated plans provided for swimming-baths 30ft. by 80ft. and 25ft. by 60ft., with 33 slipper-baths, suite of Turkish baths, and offices; the second for swimming-baths 30ft. by 85ft. and 25ft. by 64ft., with 30 slipper and Turkish baths, and offices; and the third for swimming-baths 30ft. by 82ft. 6in., and 25ft. by 62ft. 6in., with 30 slipper and suite of Turkish baths. The mayor, in proposing the adoption of the recommendation, urged that "Expert's" plan was the best, adding that if it could not be carried out for the specified sum (£7,000) the council would have the right to set the award aside. An amendment was proposed that the assistance of a professional assessor should be got, and it was pointed out that "Expert" proposed to encroach upon the front land, which was to have been sold to bring back part of the purchase-money of the site. Mr. Stead, in seconding the amendment, said "Expert" ought to be disqualified, because certain statements at the end of his paper showed that his name might be ascertained by anyone who chose to look for it. The mayor and others said they did not know the names of the authors of the plans. Mr. Stead said he knew the names of two of them, and an alderman said the names were generally known. Mr. Hughes added that the remark at the end of the paper was that "Expert" had within a certain number of years designed the Camberwell Baths, and all that was needed to find out the name was to refer to the professional journals. Mr. Baker considered that the borough surveyor, whose opinion had been taken, ought to be regarded as a professional assessor. Considerable discussion followed, but the amendment was rejected by 23 to 2, and the motion was carried by 22 to 3. The sealed letters were then opened, and the successful competitors were found to be: "Expert," Mr. Horace T.

Bonner, 29 and 30, King-street, Cheapside, London; "Mermaid," Mr. H. H. McConnell, Walsall; "Health," Mr. Samuel Loxton, Walsall. The premiums awarded were fifty, thirty, and twenty guineas respectively, and 25 sets of plans were submitted. The general purposes committee were empowered to consider whether either, and if so which, of the plans should be carried out, and whether any modifications should be made.

WIDNES.—The special committee of the Widnes Local Board, acting on the advice of their assessor, Mr. Hartley, of Liverpool, have awarded the design of Messrs. Woodhouse and Wilmoughby, of Manchester, the first premium for the proposed free public library and technical school. The second premium has gone to Messrs. Briggs and Wolstenholme, Blackburn, and the third premium to Mr. C. O. Ellison, Liverpool. The competition was an open one.

CHIPS.

On Thursday morning in last week a fire broke out at the large builders' yard of Messrs. Hayward and Wooster, Walcot-street, Bath, the firm whose tender for constructing the new municipal buildings in that city was recently accepted. A large workshop, used by joiners, and stores underneath, having a frontage of 100ft., was the seat of the fire, and this building was totally destroyed, while an adjoining smith's shop, a quantity of valuable timber, and some machinery were burnt. Messrs. Hayward and Wooster estimate their loss at £3,000, but it is covered by insurance. No cause for the outbreak is known.

Mr. C. E. Savery, M.S.A., has just completed the designs for screen and reredos to be erected at St. Peter's, Keighley, Yorkshire.

We understand the Roundhay Electric Tramway Co., of Leeds, have instructed Mr. Wm. Landless, architect, of Leeds, to get out the necessary plans in connection with the introduction of the system in a large town some distance north from Leeds.

A new eight-days illuminated turret striking clock has been presented to the new Market Hall, Gainsboro'. The makers are Wm. Potts and Son, of Guildford-street and Cookridge-street, Leeds.

The new Catholic Schools, Hull, are being warmed and ventilated throughout by means of Shorland's patent Manchester grates, the same being supplied by Mr. E. H. Shorland, of Manchester.

The tender of Messrs. Atherton and Latta, of Poplar, amounting to the sum of £18,000, has been accepted for the erection of Ward's School for Girls.

The new church of St. Augustine, situate in Queen's-road, Newland, Hull, was opened by the Bishop of Beverley on Monday. The architect is Mr. G. Gilbert Scott, F.S.A., and the edifice consists of one wide nave and one aisle. It is in the Late Decorated style, built of brick, with stone facings, and the arcades are of red Hollington stone. The interior roof is of pine, of parabolic shape. A chamber and gallery are constructed for the organ on the north side of the church. The tower is a massive structure; but want of funds prevents its completion at present. The seats are of pitch-pine. The cost was nearly £7,000.

The enlarged Technical School at Burnley was formally opened by the Mayor on Monday. The scheme has been carried out by the corporation, acting in concert with the directors of the Mechanics' Institute. About two years ago a new wing was added to the latter, at a cost of £7,000, providing a series of class-rooms, replete with all modern appliances, and now by the Technical School accommodation will be found for 500 more students, making about 1,400 in all. The school is in the old municipal buildings, which almost adjoin the Mechanics' Institute, and the whole of the interior has been reconstructed. The building is two stories in height. The cost of the newest alterations is nearly £4,000.

The London County Council adopted, on Tuesday, after a long discussion, an instruction to a committee to prepare a Bill to obtain Parliamentary powers for constructing a ferry across the Thames between Rotherhithe and Ratcliffe, the actual expense being estimated at £418,000. The subject will, however, come up again at the next meeting of the Council. It was also decided to widen the northern approach to the Woolwich Free Ferry, at an estimated cost of £31,000.

New printing works are in course of erection at Ashford, Kent, for Messrs. H. D. and B. Headley, by Mr. Henry J. Jeffery, M.S.A., architect and surveyor, Ashford, and Mr. Knock is the builder. Satisfactory progress has been made, and it is expected the building will be finished by the end of this month.

Building Intelligence.

DARTFORD.—The Roman Catholic Bishop of Southwark has recently visited the Industrial School kept by the Presentation Brothers and laid the corner stone of the new chapel. The building will be of 13th-century character. Brick will be used throughout for the exterior, and the roof will be slates, and the plan consists of a nave 53ft. long by 26ft. 6in. wide, and a chancel 23ft. by 17ft., separated from the nave by a simple moulded arch. On either side of the chancel will be two smaller arches, opening into recessed spaces for the stalls of the members of the Brotherhood. The roof of the chancel will be boarded and panelled with moulded ribs, at the intersection of which will be bosses. The altar will be reached by three steps above the general chancel level, and will consist of a simple stone mensa, gradine, and retable, above which will rise panelled and decorated reredos, surmounted by a projecting flat panelled baldachino over the altar. The floors will be laid throughout with wood-block paving. There will be ventilation on the Boyle's system, and the warming will be effected by steam, in connection with that of the rest of the buildings. The architect is Mr. Frederick A. Walters, F.S.A., of Westminster.

DUBLIN.—The new fish and vegetable markets will be opened on the 1st of November next. Outside the markets a large staff of corporation workmen are at work in widening Mary's-lane to 40ft. There are three entrances on the Mary's-lane side, one at either corner, and the central or principal one directly opposite Halston-street. The latter is of the Corinthian order, with columns, capitals, and entablature, surmounted by two figures representing Justice and Honest Trade. In the centre are the city arms. The markets are 330ft. long in the clear, with a width of 195ft. The area is spanned by eight comparatively low roofs, which are supported on 56 cast-iron columns and malleable iron girders. The floor of the markets is divided into ten large beds, which are concreted. The markets are crossed longitudinally and transversely by a couple of leading roads for carts, with a roadway across each end for vehicles delivering produce. Refreshment rooms, separate, have been provided for men and women and lavatory accommodation is also furnished. The superintendent is provided with a house and stores. Hydrants are provided all over the floors, with a supply of water for cleansing purposes. The work has been carried out under the supervision of the borough surveyor, Mr. Spencer Harty; Mr. Wilson was the architect, and Messrs. William Connolly and Son, of Upper Dominick-street, were the contractors. All the iron-work was executed by Messrs. Lysaght, of Bristol.

HARTLEPOOL.—The first section of the restoration of the tower and buttress of St. Hilda's Church, Hartlepool, has just been completed. It consisted in underpinning the tower and buttresses. The tower foundations were found to consist of round boulder stones, evidently taken from the sea-shore, and thrown in with nothing but loose soil to serve as mortar. It is not surprising that with such a foundation the tower soon after its erection (early in the 13th century) should begin to show signs of weakness. To rectify this defect, the six massive buttresses seem to have been built, but their foundations were little, if any, better than those of the tower. The foundations of the southern buttresses were made up of worked stones, filled in with soil. Amongst them were found several pieces of moulding of great interest and beauty. The foundations of the northern buttresses were of quite different material, apparently taken from the rocks on the coast, filled up with small stone chippings without any mortar. The work which has just been completed has been to take out a few feet at a time of the old rubble foundation, and to substitute for it a sound foundation of hard bricks and cement. The whole area has in this way been covered, the new foundations resting upon the rock. In order to accomplish this it was found necessary to excavate to a depth of from 6ft. to 8ft. Mr. C. Hodgson Fowler, F.S.A., of Durham, is the architect, and Mr. T. Carse has superintended the works as clerk of works. The second section of the restoration is the opening out of the eastern arch of the tower, and repairing the groined ceiling in the tower.

MORLEY, YORKS.—The foundation stone of the

Municipal Buildings was laid on Saturday by the Mayor. The buildings will comprise Municipal Offices, Town-hall, Council Chamber, Borough Court, and Police Department. The site is bounded on the east by Queen-street, on the south by Albion-street, on the north by Wellington-street, and on the west by a new road, 30ft. wide. On the ground floor there will be, on the left of the principal entrance, the town clerk's and borough accountant's offices, to the right the borough surveyor's and nuisance inspector's offices; along the north corridor are to be the borough court, magistrate's retiring room, and magistrates' clerk's rooms, with the witnesses', solicitors', and magistrates' clerk's office to the rear. The town-hall is to be on the first floor at the south-west corner, and will be 90ft. by 46ft. and 36ft. high. At the northern end will be an orchestra the full width of the room, under which are to be retiring rooms, at the opposite end a large gallery, with a balcony on each side, the total accommodation being for 1,200 persons seated. The second floor will have a large waiting hall or gallery, giving access to all the rooms. On this floor will be the reception room, with a small committee room attached, the council chamber, with councillors' ante-room and retiring-room and Mayor's parlour, with waiting room and large committee room, the latter being connected with the reception room by folding doors. On the lower ground floor rooms are being provided for the different municipal departments. The police department is to the north, and immediately under the magisterial portion on the floor above. A doorway from the prisoners' corridor will lead to an exercise ground. At the north-west corner will be the caretaker's house. Underneath a portion of the large hall will be the minor hall, to seat 600 persons, 70ft. long, 46ft. wide, and 16ft. high, with a platform at one end. A general kitchen will be provided, with scullery attached, constructed in the roof, on the south side. It is proposed to heat the large rooms by hot water on the low-pressure system, and the offices with open fireplaces. The whole of the ashlar used in the building is to be from the Morley Quarries, lined with brick throughout. The designs from which the building is being erected were prepared by Messrs. Holtom and Fox, of Dewsbury, and were selected from a number of competitive designs sent in. The contractors, and the amounts of their contracts, are as follows:—Masonry, Messrs. J. Schofield, Sons, and Co., Leeds, £12,456; plumbing, Mr. Thomas Storey, £890; joiners' work, Messrs. James Clegg and Son, £3,084; plastering, S. Johnson and Son, Mirfield, £1,060; ironwork, Messrs. Firth and Clay, Dewsbury, £348; slating, Messrs. J. Atkinson and Sons, Leeds, £288. The total amount of the contracts is £18,126. Mr. Henry Clarke is the clerk of works.

NEWCASTLE-UNDER-LYME.—St. George's Church has just been reopened, after undergoing restoration. The church, when built in 1828, had but a small recess to receive the communion table. Ten years ago, amongst other alterations, the floor of the easternmost bay of the nave was raised two steps, and had choir-stalls placed upon it to form a chancel. The objects of the present alterations have been to emphasise the chancel organ-space and the south aisle of the chancel, and to render the church more bright and comfortable. Wood vaulted ceilings have been substituted for the plaster ones over the chancel organ-space and south aisle of chancel, and these are divided from the plaster ceilings of the nave and aisles by wood traceried trusses. Over the communion-rail a traceried stone arch has been erected, and a wood ceiling has also been put over the communion end of the chancel. To still further form the chancel, oak screens have been erected, inclosing the south aisle of the chancel. The reredos-framing on the east wall of the chancel has been continued as wall-panelling along the north and south walls; in it are formed a credence niche and a sedilia, and the walling above has been lined with stone. New stone tracery has been inserted in four windows on each side of the church, and these windows, with two exceptions, have been filled with new leaded glazing, having coloured borders, and filling in to tracery. One of the excepted windows will be filled with stained glass. The interior walls and ceilings have been painted and decorated. A new stone porch is being erected on the south side of the church. The painting and decorating has been done by Mr. Wellings, of Newcastle. The screens, alterations to organ-case, and the

wall-panelling (all in oak) are the work of Messrs. Edwards. The whole of the other work has been executed by Mr. T. Godwin, of Hanley. Messrs. R. Scrivener and Sons, of Hanley, were the architects.

PAIGNTON.—The High Sheriff of Devon laid on Friday the foundation stone of St. Andrew's Church, Sans-road, Paignton. Messrs. Fulford, Tait, and Harvey, of Exeter, are the architects of the church, the first portion of which is about to be erected. The contract for this section, which comprises the sanctuary, choir, morning chapel, priests' and choir vestries, and base of tower, was secured by Mr. E. P. Bovey, of Torquay, for £2,562. The cost of the whole building is estimated at £6,550. The style is French of the 14th century. When completed, the church will accommodate 600 persons, in addition to the clergy and choir. The building will be executed in local red rock, with Box Ground stone dressings externally, and Ham Hill stone dressings internally. The flooring of the chapel and vestries will be of wood blocks, and that of the chancel will be laid in marble mosaic, while the steps to the sanctuary and the columns supporting the arches will be of Devonshire marble. Behind the altar space is provided for the erection of a reredos at a future time. The roof over the chancel and morning chapel will be of oak, while that portion of the latter which is situate in the tower will be covered by groined stone vaulting. The building will be heated with hot water, the chamber for which is included in the present contract. Mr. J. Pullen is clerk of the works.

CHIPS.

The east window of the chancel of Uppingham Church has just been filled with stained glass, representing the Ascension. The outlay has been £375.

The foundation-stone of a new Baptist tabernacle has been laid in Templemore-avenue, Belfast. The building when completed will accommodate 500 persons. The cost is estimated at about £2,500.

It is proposed to construct a vehicular bridge across the Mersey from Widnes to Runcorn. The corporation of Widnes have decided to seek Parliamentary powers to enable them to contribute £30,000, conditional on the town of Runcorn contributing a similar amount. The Lancashire County Council and the Cheshire County Council will also contribute towards the undertaking.

The Free Library at Whitechapel will be opened by Earl Rosebery on Saturday in next week, the 22nd inst. Mr. Arthur Hemmings, of the firm of Potts, Sulman, and Hennings, is the architect.

Mr. Joseph Rideal-Smith, architect, Craven Edge, Hopwood-lane, Halifax, has had the misfortune to fall down the bedroom stairs in his house and fracture his collar-bone. Mr. Smith is progressing favourably.

The town council of Hyde, Lancs, have decided this week to co-operate with the council of the local Mechanics' Institute in providing plans for a proposed technical school, the total cost of the works not to exceed £7,000.

On Saturday, John Farley, builder, of Truro, applied to Judge Granger at the Truro Bankruptcy Court for his discharge. His Honour said the Official Receiver had reported very strongly against the debtor, stating that the bankrupt had committed several defaults, and that his conduct had generally been most unsatisfactory and reckless. The discharge would be suspended for four years.

An extension of dressmaking premises in Coney-street, York, was opened on Monday. The façade of the new building is French Renaissance in style, and has a central oriel window carried from the first floor to roof level. The first floor is arranged as show and work rooms, with, at the rear, a dining-hall, having an open-timbered roof, and on the floors above are dormitories. Mr. W. G. Penty, F.R.I.B.A., of York, is the architect, and the chief contractors were Mr. T. Rawling for brick and stonework and Mr. G. Mansfield for joiners' work.

At St. Paul's Church, Wolverhampton, a memorial stained-glass window was unveiled last week. The subject is "Dorcas," and the artists were Messrs. S. Evans and Sons, of West Smethwick.

Steady progress continues to be made with the erection of the Blackpool tower. Messrs. Maxwell and Tuke, of Manchester and Bury, the architects and engineers, report that two of the tower legs are now erected to a height of 55ft., and a third one to a height of 30ft. The whole of the steelwork for the completion of the third leg, and for the gallery girders and arches, is now delivered at Blackpool, and up to the present time over 600 tons of iron and steel has been delivered.

Correspondence.

A.A. "BROWN BOOK."

To the Editor of the BUILDING NEWS.

SIR,—Noting your remarks on the above last week, I think if you look at the reports on the classes, &c., held last session, you will wonder with me where the "encouragement" mentioned by the committee is to be found. To my mind, a more discouraging record would be hard to find. Out of a total membership of some 1,200, the greatest number joining a class in the different divisions is 50, the average under 20!

In fact the A.A. is fast becoming an association of the many for the benefit of the few, very few. The new scheme is only possible for pupils. The architects' assistants, who compose the majority of the membership, are unable to give the time, and not always the money necessary. Besides, they are not so foolish as to give 20s. for what they can get for 10s., even with the inducement of allowing a discount on taking a quantity. In my humble opinion if the A.A. is to be a success, the fees must be reduced to a more democratic basis (they are much too high now, as they were low before), and the classes arranged so that a member who has little time to spare could join one or more without feeling he has dropped on sufferance among a superior order of beings who are undergoing a systematic cram.

Surely, Sir, it is better for members to study a few subjects than do nothing or go elsewhere.—I am, &c.,
AN OLD MEMBER.

COMPETITION AT LLANELLY.

SIR,—Your sensible remarks anent the way this competition has been conducted by the local authorities will be endorsed by every sensible architect. It seems a perfect farce to ask an architect of reputation to arbitrate, and then actually, when his decision is given, set to work to see if it agrees with local notions as to the designs selected being the best!

In this particular instance, as soon as Mr. Barry's decision was given, the competitors were asked to allow their designs to be exhibited in public, the names of the competitors being withheld, and I presume this was done. I can see no reason why, if competition designs are to be exhibited in public, the names of the unsuccessful competitors should be withheld. There is nothing *infra dig.* in being beaten in a fair fight; but it is most discouraging to not feel sure that the decision of the arbitrator will be loyally adhered to by the promoters of a competition.

I, in common with many other architects, refuse to go into any competition without a professional assessor; but I have recently found out to my cost that this is no safeguard to fair dealing, as the assessor's award may be set aside after all, if not in accord with local views.—I am, &c.,
C. E. SAVERY, M.S.A.

LAND SURVEYING.

SIR,—The diagram in my letter in your issue of August 5 was meant to be neither a perfectly new case nor a perfect facsimile of the lower half of Fig. 5. Being led by the clerical error in "Northman's" letter of July 15 to suppose his figures erroneous, I tried to find the relation between the variations of the two check lines by an approximate method. I did this because I did not want to use the calculus, by which alone could the accurate relation have been found.

Thinking that "Northman" wished to argue on general principles rather than on particular cases, I took F half-way between A and B for ease in calculation, the difference from its position in Fig. 5 being small. Now, the relation of variation of the two check lines alters when the error changes, and so, as is general in such cases, I took the error to be zero, or YA and Y_a coincident; this is similar to "proceeding to the limit" or "differentiating" in the complete process. The method was only approximate, as F was not in its right place, and E was considered fixed. Finding from his next letter that "Northman" evidently did not understand this method, I took his exact figures for the basis of my letter in your issue of September 23, to the conclusions expressed in which I still adhere (briefly, that the sacrifice in accuracy, which I fully admitted, was compensated for by ease and quickness of measurement). Having taken his exact figures, surely the approximate method can be left.

With regard to Fig. 4, the misunderstanding has arisen from the fact that while I measured from B to C, "Northman" measured from C to B. The direction of measurement should perhaps have been stated, though a check line, such as E D, has been thought by competent authorities to be sufficient check on a triangle such as A B C. The examples in the article on chaining were given from actual fields, as I thought it would be more interesting to the students; but perhaps it would have been better to have given the stock fields and lines of the textbooks.—I am, &c.,
Gravesend, Oct. 12. G. W. COBHAM.

Intercommunication.

QUESTIONS.

[10869].—**Tennis Courts.**—Will any of your readers kindly explain the best method of laying a gravel tennis court, what the foundations should be, and how it should be drained?—JERSEY.

REPLIES.

[10833].—**Timber and its Position.**—I would suggest that your correspondent, "E. S.," gets a piece of seasoned balk timber, have it split down the centre, and then place each piece vertically in a bowl of water, reaching to about a quarter of their height, one in the natural position in which it grew, and the other the reverse way. Let them stand in a warm room for a time, and then notice which shows signs of moisture on the top first. I would also advise him to read some authorities on timber and its growth: he would then obtain better information on the subject than I can give him through the columns of your interesting paper.—SIDNEY F. HARRIS.

[10852].—**Tidal River Bath.**—I note that above query has not yet been replied to, and on reading it through can understand why. "Tidal Water" has not given sufficient data to work upon. He has omitted to state two necessary factors—viz., the length of pipe from the filter to bath, and the level of bottom of bath with respect to water level at outlet from filter at commencement of the hour. A simple outline sketch would be advisable, as for example, thus—

Will "Tidal Water" kindly supply this information?—N. B. D.

[10857].—**Testing Drains.**—"C. E. H.," on p. 512, approves of the use of ether, and considers it better than peppermint. Both the ether and peppermint tests, however, appeal only to the sense of smell, and many people are very deficient in that sense. Further, these mere smell tests are very indefinite, and with them it is often difficult to localise, and to judge of the extent or character of the leakage. The smoke-test, again, applied with a proper machine and with sulphur mixed with the cotton waste, appeals to both the senses of smell and sight, and often shows at once where the fault is. This is very useful where the fault is small, and prevents reckless and unfair condemnation of fittings. Where the fittings are really bad, then the smoke filling the premises gives ocular demonstration which it is difficult to get over. The ether and peppermint tests are too indefinite, in my opinion, for a court of law: with them fittings have been condemned in a mass, while all that was wrong was a small accidental perforation of the soilpipe with the point of a nail, which, when discovered, was rectified in a few minutes with a drop of solder.—W. P. BUCHAN.

[10864].—**Measuring Fees.**—The builder is supposed to pay half the fees for measuring up extras, unless otherwise agreed.—H. H.

[10865].—**Ornament.**—"Student" could not do better than attend the classes on Applied Art at the London University. The first necessary is to select good ornament, and for this purpose the Architectural Museum, Westminster, King's College Museum, and especially the South Kensington Museum should afford excellent examples for drawing and study in "Student's" leisure hours. For books, Owen Jones's "Grammar of Ornament" and the works of Wornum and Ruskin are recommended; but I should advise "Student" first to go through a course of lectures and to study Ward's "Principles of Ornament" for the elementary principles. Ornament should be taught by a proper method. Copying ornament from books and buildings promiscuously, and trying to design it, before acquiring a general knowledge of art, is unsatisfactory and misleading. A study of nature, especially plant form, is absolutely essential.—G. H. G.

[10866].—**Conductor for Lightning.**—Providing the earth is moist, a conductor should (after having been brought out from the line of the building about 20ft.), where practicable, be taken to a depth of from 5ft. to 6ft., and the end should be riveted to a copper plate (being in proportion to the size of the conductor employed). It is desirable to surround the wire and the plate with coke (from two to three bushels), as it tends to prevent the copper from very rapid corrosion in a moist situation, and at the same time provides a large conducting mass. The above suggestions are in accordance with some of the greatest acknowledged authorities on lightning conductors. It is, however, impossible to lay down

for "Architectus" any very definite rule without knowing the particulars of the situation of the proposed conductor, which might be influenced by any of the immediate surroundings, such as adjacent water or gas mains, in either of which cases the conductor should be attached.—C. E. H. A. and S.

[10868].—**Conductor for Lightning.**—According to one authority, the conductors should terminate in earths, offering each about 18sq.ft. of external surface: these may consist of copper plates about 3ft. square, riveted to the conductor's ends, and buried in the wet soil from 15 to 25ft. from the building. When the water-level is deep, special wells should be sunk for the earth plates, and these wells ought to be carried down several feet below the water-level in the driest seasons, and the lower portion of well should be built dry. The above are quoted from Rules for Buildings where the manufacture of explosives is carried on, and are issued by the War Department, so they are perhaps unnecessary for ordinary buildings. Each rod should be connected to earth by the shortest path outside the building, and if practicable it is well to carry the conductor down that face which is most exposed to prevailing wet. "Architectus" may consult Anderson's work or the new work on Lightning Conductors by Oliver D. Lodge, D.Sc., LL.D., &c., published by Whittaker and Co.—B. FRANKLIN.

[10867].—**Sliding or Lifting Shutters.**—I have seen good examples of both. The lifting shutter casing is rather draughty, but really forms a good fresh-air inlet sometimes. It is hung in precisely the same way as sliding sashes in front of the sash frame, and is really a boxed frame or casing in which the two shutters slide side by side or one in front of the other. A flap shuts down over the casing when the lifting shutters are not in use. The upper rails of both when down are level with the window sill. A framed back is placed in front of the casing. The upper shutter is nearest the back, and the other inside between the parting bead and a bead fixed on to the inside lining of sash frame. Sliding shutters which slide laterally have recesses or boxes on each side, the disadvantage of which is they occupy a large space on each side of the window, which cannot be always obtained. I prefer the lifting shutter for a country house. The casing or boxing has usually to be sunk below the floor level, and there should be a cement or non-porous material for the outside and bottom of casing.—G. H. G.

CHIPS.

At the monthly meeting of the local board of Warminster, held on Monday, £50 was granted to the surveyor (Mr. Long) on account of extra services rendered by him in connection with the installation of the new engine, &c., at the Waterworks. It was reported that the actual cost of the new works would be £1,520, as against £1,550, the loan sanctioned for that purpose.

The Right Rev. Bishop Smith, Bishop of Dunkeld, laid on Monday the foundation stone of the new Convent of Our Lady of Mercy, which is to be erected at Lawside, near Dundee.

Alterations have been made to the union workhouse at Lincoln, embracing the ventilation, which is now carried out on the Boyle system, the latest improved form of the self-acting air-pump ventilator being adopted for the extraction of the vitiated air.

At Tuesday's meeting of the Middlesbrough County Council, a long discussion arose on an amendment moved that a minute, requesting Mr. C. H. Howell, architect, of London, to come to Middlesbrough to meet a sub-committee on the subject of accepting a commission for the erection of the proposed asylum, be not confirmed. Eventually the minute was confirmed, and it was further decided to submit a number of sites to Mr. Howell to report upon.

The Bristol Town Council decided on Tuesday, by a majority of 42 to 2, to promote a Parliamentary Bill to carry out the dock extension scheme at Avonmouth and Bristol. A resolution pledging the council to the Corn-street and Broad-street site for municipal buildings was rescinded, and a special committee was appointed to consider and report as to the relative area, cost, and advantages of other sites available. By a casting vote it was resolved to spend £1,200 on improving the accommodation of the Bristol Council-house; but notice to rescind this was given.

A coffee tavern has just been built in Phoenix-street, Lancaster, from plans by Mr. E. Howard Dawson, A.R.I.B.A., F.S.I. The work has been carried out by local tradespeople at a total cost of £2,000.

At the meeting of the Kettering Board of Guardians on Monday, Mr. J. A. Gotch, F.S.A., presented plans for additions to the workhouse, including a new infirmary, and he was instructed to prepare alternative plans to include a new board-room.

The proposed memorial in Winchester Cathedral to the late Bishop Harold Browne is to be a recumbent effigy of the deceased Prelate, and a committee has been formed to collect the necessary subscriptions.

Memorial stones of the new free library and public baths and wash-houses for Westminister were laid on Wednesday week. Mr. F. J. Smith, of Great George-street, S.W., is the architect, and Messrs. Lough, Simpson, and Co., of Brompton-road, are the builders.

Legal.

THE PRIVATE STREET WORKS ACT, 1892.

CASES are constantly arising over disputed points as to the paving, &c., of new streets and the liabilities of owners of frontages under the Public Health Acts. So complex is the subject that a book dealing with it separately and, as far as possible, exhaustively has come to be required. In "The Law and Practice of Paving and Making Good Private Streets," by Mr. William Spinks, A.M.I.C.E., &c. (Spens, 125, Strand), we have such a work. In his third edition, just issued, the author has added as an appendix the very important Private Street Works Act, 1892, of last session. This statute, which is to be read with the Public Health Acts, can now be adopted by any urban sanitary authority after certain formalities, and when adopted it will supersede those well-known sections, 150-152, of the Public Health Act, 1875, upon which they have hitherto had to depend. In the same way the Local Government Board may extend the new Act to rural districts. Mr. Spinks has clearly taken great care to bring his book down to date, and to note up all decided cases. He has also given some notes upon the new Act, which has in law been in operation since the date of its passing, on 25th June last; though, of course, it has not yet had time to be generally and practically adopted. Seeing that this adoption conveys many and various advantages as compared with the sections of the Public Health Act, 1875, it is pretty sure of a welcome by most of our urban sanitary authorities; and, therefore, its provisions will become of very general and pressing interest to all concerned in building operations.

The new Act provides for a provisional apportionment of the estimated expenses among the premises liable to be charged, so that objections can be taken by parties interested before the work is begun, instead of after it was completed, as under the older plan. The statute opens a very wide question when it declares in section 10 that the urban sanitary authority may consider in its apportionment of the expenses the greater or less degree of benefit to be derived by any premises from such works, and may also take into account the amount and value of any work already done by the owners or occupiers. This clause will afford a means of equitably adjusting the apportionment, without being bound by the iron rule of frontages. Powers are also given for including necessary incidental works in the estimates for paving, &c., and for charging a 5 per cent. commission for surveys and superintendence. Another important section is that under which an urban authority may, if it thinks fit, contribute the whole or portion of the expenses of any private street works, and pay the same out of the general district rate. Section 19, which gives power to the urban authority to adopt a private street which has been properly paved, &c., as a public highway, is also likely to be extremely useful. In short, there is a good deal in this new statute well worthy of careful attention.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

A SUFFERER.—DRAINS.—WARRANTY.—This question really turns on matters of fact and evidence. If you can prove the landlord's express warranty as to the drains and the sanitary condition of the house as stated, you would have a good ground of action, and you should sue him for damages for breach of his express warranty as to the state of the drains, and upon his false representation as to its sanitary condition. You should at once consult your solicitor.

ARCHITECT.—REMUNERATION.—The usual rule is that if the intended building is abandoned after the completion of working plans and specifications, the architect should get 2½ per cent. commission, and that if it has gone as far as delivery of tenders he should have 3 per cent. But this is of course subject to any bargain that may have been made.

The judges at the International Exhibition which has just closed at Douglas, Isle of Man, have awarded the gold medal of honour as well as a diploma for excellence of work as exhibited in sculptured alabaster and carved oak to Mr. Harry Hems, of Exeter.

LEGAL INTELLIGENCE.

GARDENS AS ENCROACHMENTS ON STREETS.—At the Manchester county police court on Saturday Mr. Oliver Heggs, builder and contractor, Levenshulme, was charged with infringing the Public Health Act. The offence alleged was that in contravention of the by-laws of the Levenshulme local board, the defendant omitted to make two streets which he had laid out in Levenshulme—Carrillgrove and Worsley-grove—36ft. wide. Evidence was given to the effect that when defendant originally submitted his plans to the board's surveyor the distance from house to house in these streets was 36ft., but it was indicated that gardens were to be made on this scheme in front of the houses. The plans were rejected. Subsequently they were resubmitted without the provision for gardens, and the board approved them. After the houses were built the defendant, however, caused gardens to be made, which reduced the width of one street to 15ft. 6in., and of the other to 18ft.—In cross-examination the board's surveyor admitted that many streets in Levenshulme made since the by-laws were framed had gardens in front which reduced their width to much less than 36ft., one of these belonging to a member of the local board. While admitting the offence, defendant's solicitor urged palliation on account of both streets being *cul de sac*. He contended that the houses were more cheerful and picturesque on account of the gardens, and that no injury was occasioned to anyone. The case was adjourned for a month to see if some compromise could be arranged.

HALF COSTS OF WALL TO BE PAID WHEN UTILISED.—At the Brompton County Court on Wednesday week, before the deputy judge, Mr. Cooper Wyld, Henry Fowler, builder, of 47, Davisville-road, Shepherd's Bush, sued Robert Julian, also a builder, living at Ashchurch-grove, for £25 for trespass. The plaintiff deposed that in 1880 he erected four houses in the Davisville-road, and the property was inclosed by a wall. Some time after the defendant put up houses on land which adjoined, and plaintiff then asked him to pay half the cost of the wall, £25. Defendant offered £15, and plaintiff refused. Plaintiff communicated with the defendant again, and he was then told that Mr. Julian did not intend to pay anything. Defendant: I offered him the £15, I know, and then a gentleman who had bought one of Mr. Fowler's houses said it was his wall, and I ought to pay him. I wrote to my solicitor, and he advised me to repudiate the liability. Mr. Stevens, the district surveyor, said the defendant was responsible to the extent of £23. Judgment for the plaintiff for £23, and costs.

DAMAGE AGAINST A BUILDER.—At the Southwark County Court on Monday, before Judge Holroyd and a jury, Mrs. Sellwain, the wife of a carman, of Darwin's-buildings, Old Kent-road, sought to recover £30 from Mr. Amos Eaton, a builder, of 5, High-street, Whitechapel, as damages for personal injuries sustained by her through the negligence of his servants. Some bricks fell from a building in course of erection by defendant in Middlesex-street upon plaintiff, injuring her shoulders and back. The jury awarded £25 damages, and costs were allowed.

ARCHITECTS NOT PERSONALLY LIABLE.—*Constantine v. Brown.*—At the City of London Court, on the 5th inst., T. J. Constantine, of 61, Fleet-street, claimed £215s. 6d. of the defendant, Edward Brown, architect and surveyor, of 5, Elder-street, Spitalfields, for cleaning out an old range and putting in a new one. The defendant said he gave the plaintiff the order in his capacity as architect for the owner, a Mr. Proctor. He had given the plaintiff many previous orders, and they always looked to his (defendant's) clients. He was not personally responsible. Mr. Commissioner Kerr: An architect does not make himself personally responsible. You must sue Proctor. Judgment for the defendant, with costs.

ARBITRATION AT EDINBURGH.—The proceedings in the arbitration between the Corporation of Edinburgh and the North British Railway Company as to the price to be paid by the latter for the ground taken by them in Princes-street Gardens, have been closed so far as the taking of evidence is concerned. The oversman in the reference is Lord Shand; Mr. Dunlop, Westminster, is the arbiter for the corporation; and Mr. James Davidson, Saughton Mains, acts as arbiter for the railway company. The witnesses heard on the later days, since our report of last week, p. 513, included Hamilton Beattie, architect, Edinburgh; B. Hall Blyth, C.E., Edinburgh; James Barr, C.E., Glasgow; Wm. Ormiston, ordained surveyor, Edinburgh; Haldane Beattie, builder, Edinburgh; H. E. Milner, landscape gardener, Westminster; Wm. Thomson, Cravenfords; and David Low, horticultural builder, Edinburgh. The arbiters, Messrs. Dunlop and Davidson, held a private meeting on Tuesday in Dowell's Rooms, Edinburgh, with the object of adjusting their decision. After consideration of the case extending over three hours, they were unable to agree as to their valuation, and the matter will accordingly be referred to Lord Shand, the oversman.

WATER SUPPLY AND SANITARY MATTERS.

NORTHAMPTON.—At a town council meeting held at the Guildhall on the 3rd inst. it was resolved, by a majority of 17 votes to 6, to adopt Mr. Bailey Denton's report to increase the area of the Sewage Farm by the purchase of 200 more acres of land, and to purify the sewage of the town by means of wide irrigation and intermittent filtration, and not to have recourse to the "international" system of sewage purification by means of ferrozone and polarite beds.

CHIPS.

The marriage of Mr. Ralph Nevill, F.S.A., of Rolls-chambers, W.C., to Mary Beatrice, daughter of George T. Tweed, of Honiton, took place on Wednesday at St. Barnabas, Kensington.

The health of M. Paul Dubois, Director of the School of Fine Arts, Paris, who has been ill for some time past, underwent a sudden change for the worse on Tuesday evening. His condition causes great anxiety.

The memorial-stone of the institute in connection with the Canal Boatmen's Friendly Society of Scotland, which is at present being erected at Port-Dundas, Glasgow, was laid on Tuesday. The premises are being constructed at the corner of Port-Dundas-road and Dobbie's Loan. There will be a coffee-room and library, rooms for committee, and a hall capable of seating 250. There are also on the basement floor a recreation hall and drying-room, and also a kitchen and lavatories. Messrs. John Honeyman and Keppie, Glasgow, are the architects. The cost of the ground, building, and furnishings will be £5,000.

Mr. Arnold Taylor, Local Government Board Inspector, held an inquiry at the Rochdale Town Hall, on Thursday, as to an application by the Rochdale Corporation to borrow £65,000 for gasworks purposes (the provisional order having been already granted), and £12,000 for street widening and improvement.

A new peal of bells hung in the tower of Machynlleth parish church as a memorial were consecrated on Friday. The tower originally contained three bells, which were cast in 1745, but two of them had been cracked for some time past. The work of casting the bells was intrusted to Mr. Barwell, of Birmingham.

The decorations of St. Saviour's church, Falkner-square, Liverpool, have been completed under the superintendence of Mr. Charles Aldridge, F.R.I.B.A. In the dome of the chancel where the decorations have culminated, are seven circular panels representing the Four Evangelists, also St. Peter and St. Paul. In the centre of these is a stained-glass panel of the Saviour. These have been painted by Mr. Lonsdale. The alterations have been carried out by Messrs. Shrigley and Hunt, of Lancaster.

Two houses in Cumberland-walk, Tunbridge Wells, have just been remodelled to form a vicarage for King Charles's Church. Mr. Ladds was the honorary architect, and Messrs. C. S. Strange and Sons were the contractors.

M. E. Signol, a well-known French painter of sacred subjects, has died at an advanced age. A pupil of Blondel and Baron Gros, he obtained the Prix de Rome sixty-two years back. Between 1838 and 1844 he did much work for the embellishment of the galleries at Versailles. His "*Femme Adultère*," now in the Luxembourg, was the most popular picture of the Salon of 1840. In that year he was employed in decorating the Madeleine, and he subsequently worked in other Parisian churches. To the Universal Exhibition of 1855 he contributed largely.

About fifty members of the Architectural Association visited St. Alban's Cathedral on Saturday week, and were conducted over the building by Mr. James Neale, F.S.A.

A bust of the late Miss Constance Naden, daughter of a Birmingham architect, and mounted on a black marble pedestal, has been placed in the Mason College at Birmingham. Mr. William Tyler, of London, was the sculptor.

A new organ, built by Messrs. Young, of Manchester, at a cost of about £300, has been placed in the Rishworth Baptist Chapel.

The memorial-stone of the new markets for Halifax was laid on Friday. The work is being carried out from plans by Messrs. Leeming and Leeming, of London and Halifax, selected in competition. Mr. Charnock is the contractor. The mayor, when laying the stone, mentioned that the land had cost £44,106, the contract for the erection of the arcades leading from Russell-street was let for £12,548 16s. 10d., that for the general market for £4,045 6s. 2d., whilst architects' commission and other extras would amount to £4,329, giving a total for the buildings of £60,923, or about £20,000 in excess of the original estimates.

Our Office Table.

THE change of venue of the annual conversation of the Architectural Association from Westminster Town Hall to Mr. T. E. Collcutt's recently-completed Imperial Institute at Kensington proved a great attraction, and the number of members and their lady friends welcomed to the Institute by Mr. H. O. Cresswell, as president, and the committee, on Friday evening, was nearly double that of recent years. For such a gathering the Institute is not an ideal building, although adapted for its normal purpose. The lack of a general assembly hall as a rendezvous for acquaintances is a great drawback. The staircase is not monumental in scale, and too much space is taken up by the wide corridors. Truth to tell, beyond the arrangement of the building itself, there was little to interest the crowd of visitors. Mr. J. L. Robinson's photographs of the recent Taunton excursion were on view in the temporary committee room at the further end of the highest floor, and on the first floor the eastern wing was occupied by the exhibition of Indian art metal work, soon, it is understood, to be dispersed. The western wing of the building is given over to a trade display of Oriental fabrics, where the plentifully distributed cards of the various firms, and the placards "All these goods are for sale," clash with one's conception of what should have been the outcome of all the touting and squeezing for funds for a national memorial of her Majesty's Jubilee, and are unworthy of the *prestige* even of a nation of shopkeepers. At present the Imperial Institute only represents India, none of the Colonies showing any exhibits. In the comparatively small end room of the western corridor on the first floor entertainments were given at intervals during the evening by Dan Godfrey's orchestral band, and also by the body of artistes calling themselves the Spanish serenaders, who gave some excellent songs and instrumental selections.

MANY who have little sympathy with hero and relic worship will, nevertheless, feel satisfaction in the assurance just given that Nelson's old flagship, the *Foudroyant*, will be brought back to this country and permanently moored in the Thames as a specimen of our hearts-of-oak navy and as a Nelson museum. A guarantors' committee has procured the ship for £5,000, and it is intended to offer her to the nation as a gift, refitted with masts and riggings of the type used a century since. The Teutonic successors to Daniel Quilp have already removed her upper deck, but the rescuers of the old tub assert that they will have no difficulty in securing and replacing the original timbers, and even though the vessel ought to be labelled "Made in Germany," it will be a picturesque and interesting object on the Thames.

THE new School of Applied Art in Edinburgh will be opened on Friday in next week. The school is started under favourable auspices. The Board of Manufactures for Scotland has granted rent free two of the largest rooms in the Royal Institution as a school-room and lecture-hall; the City Council of Edinburgh has voted a grant of £1,000, and other subscriptions to the extent of nearly £1,500 have been raised chiefly by professional men and craftsmen in the city. The school is established, according to the prospectus, for the purpose of "imparting to architects, decorators, sculptors, wood-carvers, metal-workers, silversmiths, plasterers, bookbinders, printers, glass-painters, &c., a knowledge of art design as applied to industries." This winter, in commencing operations, it is intended that the basis of the teaching shall be an education in common in Classic, in Renaissance, and Mediaeval arts. The education in the new school will begin practically where the instruction given in the local Board of Manufactures School of Art leaves off; and will embrace for its leading feature continuous instruction in art styles from the Classic period until now. Dr. Rowand Anderson, who, with Mr. Inglis, has selected the nucleus of a collection of casts, will act as director of the classes, assisted by Mr. Frank Simon and Mr. John Watson as draughtsmen, and Mr. Robert Innes as modelling assistant. The library of the Edinburgh Architectural Association has been removed to the new school, and will, with the art library formed by the Board of Manufactures, be available free for consultation.

At the close of the paper read by Mr. Okoshi

at the opening meeting of the Japan Society on Wednesday evening, at the Society of Arts, Sir Edward Reed in the chair, on "The Proverbs and Popular Sayings of the Japanese People," a demonstration was given of a series of wall-pictures, bronzes, carvings in ivory and wood, objects in lacquer, and ancient New Year's cards and wood-block colour prints of Japan, in which the wisdom, wit, and quaint humour of the Japanese are artistically rendered. The proverbs were illustrated from some hundreds of art objects belonging to the historic art of Japan, selected from the collection of Mr. Ernest Hart, and a series of proverb cards used as a game among the young people of Japan. The wall was hung also with brilliant but delicately-coloured portraits by Moronobu, Yeishi, Toyokuni, and other leading painters of Old Japan, of celebrated and dangerous beauties arrayed in all the colours of the rainbow. These pictures were painted in the 17th, 18th, and 19th centuries.

THE agitation against the Registration of Architects Bill by the Builders' Association of Victoria has some meaning to those who can read between the lines. The Bill itself, as we have before said, has been warmly espoused by all the independent architects of the colony; it has been redrafted into a form that has disarmed all opponents; but all at once the contractors have displayed hostility to the Bill. Is there not a selfish motive underlying this opposition? The competing contractor of a certain class would naturally oppose any attempt to make architects more efficient and competent; they would also look with dismay on any measure which would protect the public against the employment of any but skilled architects. We cannot believe that such a motive has prompted the higher class of contractors of Victoria, but only those who, as our contemporary the *Australasian Builder* puts it, thinks that a "builder is as good as an architect," and should be allowed to take architects' work.

THE Plumbers' Company are to be congratulated upon sharing, to the extent of £20,000, in the bounty of the late Mr. Robert Berridge, of Cambridge, who has left upwards of £150,000 for furthering the spread of sound views and practice in sanitary matters. Only the interest of this sum will be used, and that use is by the terms of the bequest to be confined to Great Britain. By this legacy the Plumbers' Company will be able to extend their scheme for the improvement of the plumbing trade by the establishment of additional district councils and technical classes. Under the same legacy £10,000 has been allowed to the Sanitary Institute, £4,000 to the Society of Medical Officers of Health, £3,500 to the Association of Public Sanitary Inspectors, and £10,000 each to the chairs of hygiene to be founded by University and King's Colleges, London.

MR. ARTHUR HILL, B.E., F.R.I.B.A., presided at the last meeting of the Munster District Council for the National Registration of Plumbers, held at Cork a few days since. A letter was read from the Worshipful Company of Plumbers, London, stating that Mr. W. Kaye Parry (architect), of Dublin, was at present engaged in preparing some slides to illustrate his forthcoming lecture on "Domestic Sanitation" at Cork, and that the same would be ready in about a couple of months. A lengthy discussion took place in connection with the opening and working for the session of the plumbers' workshop, now fitted up at the School of Art, and the classes connected therewith, and it was decided that the sub-committee previously appointed be empowered to draw up a syllabus of instruction in two grades for the pupils attending the class, and to make such arrangements in reference to the teaching of the different branches of the work required as they may consider necessary.

The town council of Manchester have accepted a tender for £46,410 for the erection of labourers' dwellings in Oldham-road.

Mr. J. Brooke, of Crawe, has been appointed surveyor to the local board of Northwich, at a salary of £190 a year. There were 81 candidates.

The laying of the memorial stone of the Church House, in Salop-road, Welshpool, right opposite the parish church of St. Mary, by the Countess of Powis, took place on Thursday in last week. The architect is Mr. T. E. Pryce, Gray's Inn, London; and the contractor Mr. William Roberts, Welshpool. The amount of the building contract was £1,200.

DEATH.
VERITY.—On the 12th inst., at Meadowside, Hutton, near Liverpool, William Verity, Architect. Aged 32 years. R.I.P.

The Architectural Association, 9, Conduit Street, W.; and 56, Great Marlborough Street, W.

THE ARCHITECTURAL ASSOCIATION COURSES OF LECTURES, CLASSES, and STUDIO INSTRUCTION are now commencing. The Courses are both Elementary and Advanced, and are designed to provide a sound professional education, supplementary to that to be obtained by the prevailing system of pupillage. The Course, which is in four divisions, is progressive and consecutive, and the instruction is given by Lecturers and Instructors of known ability.

DIVISION I.
LECTURES and CLASSES.—The Orders of Greek and Roman Architecture, Building Materials, Perspective, Physics.

THE STUDIO.—Drawing from Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Plane Geometry, Criticism Meetings.

DIVISION II.
LECTURES and CLASSES.—English Architecture, Materials, Elementary Ornament and Colour Decoration, Strength of Materials, Stresses and Strains.

THE STUDIO.—Designs based upon Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Solid Geometry, Criticism Meetings.

DIVISION III.
LECTURES and CLASSES.—The History of Architecture, Materials, Colour Decoration, Sanitary Science as applied to Drainage and Water Supply.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Perspective and Sciography, Constructive Masonry, Criticism Meetings.

DIVISION IV.
LECTURES and CLASSES.—The History of Architecture; Sanitary Science—including Ventilation, Lighting and Heating, Painting, Sculpture; other Arts allied to Architecture; Professional Practice—including Legislative Enactments relating to Building Contracts.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Drawings of Ancient Buildings from actual measurement, Graphic Statics and Perspective, Criticism Meetings.

EXTRA SUBJECTS.
LECTURES and CLASSES.—Plane and Solid Geometry, Geology, Mensuration, Land Surveying and Levelling, Chemistry of Building Materials, Quantity Surveying—including the Preparation of Estimates, Discussion Section.

THE STUDIO.—Sketching and Measuring, Elementary Water Colour Class, Water Colour Class, Modelling.

A Pamphlet, containing full particulars of the curriculum, may be obtained free on application to the Hon. Secs., at 56, Great Marlborough-street, London, W. Fees must be paid in advance, and passes may be obtained at the Offices of the Association, between Ten a.m. and Seven p.m.

October 21st, the ANNUAL GENERAL MEETING of the Association will be held at 9, Conduit-street, W., at 7.30 p.m., when the award of prizes for the past session will be announced, and the President will deliver his address. The prize drawings for last session will be on view.

ERNEST S. GALE,
F. T. W. GOLDSMITH, } Hon. Secs.

Trade News.

WAGES MOVEMENTS.

COLNE, LANCS.—Messrs. Hawley, builders and contractors, of Colne, who have an extensive building in the town, have given notice to the masons in their employ that their wages will in future be reduced from 9d. to 8½d. an hour.

HIGH WYCOMBE.—A meeting of carpenters and joiners was held at the Swan Inn on Saturday evening last, when, after hearing an address from Mr. Charles Matkin, it was decided to organise a branch of the General Union of Operative Carpenters and Joiners in the town.

ROCHDALE.—Over 1,100 quarrymen came out on strike on Friday in the Whitworth Valley, leading from Rochdale to Bacup. It appears that eight quarry-masters, in the neighbourhood of Millgate, Shawforth, and Freith, have given notice to their workmen of a reduction of wages, and the notices expired on Monday, the 11th inst. A large number of quarrymen who are on strike in the Slacksteads district went over into the Whitworth Valley on Friday, and persuaded the quarrymen there to come out.

CHIPS.

The first sod of sewerage works for Chepstow was cut on Friday. Mr. C. Walker is the engineer, and the contract has been taken by Mr. Whalley for £3,500.

The peal of ten bells in the central tower of Hereford Cathedral have just been restored, having been rehung and refitted by Messrs. Blackburn and Greenleaf, of Salisbury. The treble bell has been recast.

The Stockport town council have adopted the sewerage scheme for the borough prepared by Mr. A. M. Fowler, C.E., the cost of which, it is estimated, will be £80,000.

Of the sixty-four oaken statuettes required to fill the tabernacle work of the choir-stalls and bishop's throne in Lincoln Minster, all but sixteen have been given or promised, and will very soon be in their places.

Mr. J. Burns, M.P., announced at a meeting held in Battersea on Monday night that if the local vestry and the County Council would raise £10,000 towards the sum required for the purchase of the Albert Palace, an equal sum would be given by a person whose name he was not at liberty to disclose.

Holloway's Pills purify the blood, correct the bile, give tone to the stomach, excite a healthy appetite, produce sound sleep, and impart increased energy to both mind and body. The admirable properties of these far-famed Pills are too highly appreciated to require any encomium here, as they are resorted to by rich and poor of every nation.

RANDALL'S SOLUTION FOR MORTAR Supersedes Cement. Sets in Frost, and Hardens Stone or Brick-work.—Depot: Kentish Town-road, N.W. And Eastlea, Poole, for Bournemouth District.

FRIDAY, OCTOBER 21, 1892.

ST. MARY'S HOSPITAL—CLARENCE WING COMPETITION.

FIVE designs have been submitted for the proposed Clarence Memorial Wing of St. Mary's Hospital, Paddington, though the committee have not yet come to any decision on the plans, and we hear it is not yet settled who the referee is to be. The new Clarence wing is to be erected on a plot of ground on the south-east side of the present hospital in Cambridge-place, and its main frontage will be towards Praed-street. The main departments required are a medical college with residences at the west end of the wing, an out-patients' department, special wards for male and female patients, nurses' accommodation, besides the usual requirements of laboratory, dispensary, stores, kitchen, offices, &c. The designs submitted are by Mr. H. H. Collins, Mr. Henry L. Florence, Messrs. Stephen Salter and Adams, Messrs. Searle and Hayes, and Mr. Keith D. Young.

The plans indicate generally a careful study of the requirements of the hospital; but are of various degrees of merit in the mode of classification and in the arrangement of the departments. One of the ablest designs—both in respect of the general plan and the elevation—is that under the motto "Economical Administration." The principal entrances are in Francis-street and Praed-street. The former shows a well-arranged registration hall with entrances for male and female patients, with clerks' offices on either side, leading into a large out-patients' waiting-hall 70ft. by 33ft., with consulting and dressing-rooms on each side for the two classes of patients. Four large consulting-rooms are provided, two on each side, with a group of dressing-rooms between each pair. This waiting-hall occupies the centre of the wing at this end, and is placed in line with the axis of the wing. The main entrance-hall in the centre of Praed-street front is commodious, and enters the wing at the end of the out-patients' hall, a corridor giving access to the senior medical staff and secretary's departments, a medical waiting-hall, and dispensary. A corridor connection from the old building is shown.

The first-floor plan shows the out-patients' waiting-hall, glazed over, which gives it a good top-light. The residential medical college is placed at the Francis-street end, and returns some distance in the rear; then follows the matron's department to the Praed-street entrance, and lastly the offices of secretary and his residence at the corner of Cambridge-place. The medical college is chiefly divided into sitting and bedrooms. Connection with the present hospital wards is shown by a corridor near the main staircase landing. On the second floor the main portion of the block towards Praed-street contains the residential medical staff rooms. On the third and fourth floors the wing is no longer continuous, but is broken up into special semi-isolated blocks of wards forming the centre part of the Praed-street façade. These wards are circular-ended where they detach themselves from the medical college at one end, and the lying-in department at the Cambridge-place end. From a hygienic point of view, this detachment of the special wards has much to recommend the plan. A feature which the author has turned to the best account is the architectural grouping of his main

façade. The two wards are placed on the same axis lengthwise, one side of them facing Praed-street. One ward accommodates seven beds for skin diseases, and the other eight beds for ear and throat diseases. Between these wards, running transversely to their axis, is a corridor connecting the second floor of the present hospital. Towards Praed-street a balcony, with columns, is shown, for the use of patients, and between each pair of wards is a sister's room, food and linen stores, and bath-room on one side of the connecting corridor, while a ward scullery and staircase is arranged a little farther along the corridor. About mid-way between these outside wards and the present building are two circular wards for ophthalmic cases, five beds to each, and these wards are placed one on each side of the corridor. At the angles of the outer wards, isolated lobby conveniences for slops and closets are shown, these being octagonal in plan, and made to form turrets at the angles of the end blocks, in Praed-street, a very artistic mode of treating them. We may simply add that the lying-in block for six beds at the corner of Cambridge-place forms the corresponding wing to the college, and completes the wing on this front. In the upper floors are the nurses' cubicles. The external design is shown by elevations of red brick and terracotta of five main stories, with high hipped roofs over the pavilions and end blocks. A centre turret crowns the central roof; the end blocks are well massed, with octangular turrets at the angles, these being utilised as conveniences. The corbelled-out balcony to the central pavilion portion is a good feature, and the circular ends of the pavilions are artistically managed, and give variety to the main front. A well-drawn ink perspective is sent. The high roofs are of green slates, which will harmonise with the red brickwork.

A very elaborate set of plans is that bearing the motto "Ad Rem." There is much less of that skilful grouping and classification we have in the first mentioned; the plan is broken and irregular, and the upper corridors and special wards are less studied. A large waiting-hall, 50ft. by 39ft., with medical and surgical consulting-rooms on opposite sides, with dressing-rooms in connection, occupies the western block. The registration-hall, with waiting spaces for male and female patients is provided. A long corridor along the Praed-street side, with main entrance to senior staff and secretary's rooms, has a dispensary at the end, and this corridor is well lighted by large courts. The entrance for lying-in department is at the Cambridge-place end, with reception and undressing-rooms, lift, and conveniences. On the first floor the medical college is at Francis-street end, then follow the administration department and the special wards for ear and throat, 39ft. by 22ft. each, for eight beds, and two for ophthalmic cases, and the lying-in wards. These wards are placed lengthwise to Praed-street, with access by a glazed back corridor, and a balcony in front. The corridors are well lighted by the courts. The access and conveniences are generally well considered. The same arrangement is repeated on the next floor. Unfortunately, the irregular grouping of the plan has marred the elevation towards Praed-street, and rendered it extremely lop-sided and ungainly. There is no balance. The lying-in department at the Cambridge-place end is one story higher than the rest of the façade, and has an octagonal turret at the corner, while at the other end there is no wing, but another angle turret. The main entrance is crowded and one-sided, producing a jumbled appearance. The details of ventilation and warming are shown in a special sheet of large-scale drawings.

Next in order of hanging is "In Memoriam," in which the author has intro-

duced a departure by placing his wards in four pavilions at right angles to Praed-street, and at certain intervals, these being utilised as garden spaces—an admirable idea if more area were obtainable. The out-patients' department is in the basement, where a large waiting-hall and consulting-rooms are shown. The principal ground-floor entrances are too narrow, and the main corridor appears from a general view of the plan to be badly lighted; the medical staff corridor in centre would be dark. We also object to the corridors being set side by side. The first floor shows accommodation for the college bedrooms, matrons' and nurses' cubicles, in isolated pavilions separated by gardens; the next floor repeats the nurses' cubicles, and the third floor is appropriated to the special wards for six beds, each connected by a corridor with conveniences between the pavilions, of which there are four. Externally, the Praed-street front is shown in a coloured elevation representing red brick as the material, the four five-storied blocks or pavilions having their ends to the street. From a hygienic and architectural point of view, this arrangement of blocks would have the merit of imparting variety and good light and ventilation, as each ward could be cross-ventilated; but the plan of the departments and official and administrative offices is not satisfactory on the whole.

"Fleur de Lys" is a well-devised and drawn set of plans. There is a good main entrance at the end of Praed-street, near Cambridge-place, with corridor running along the block. The consulting and examining rooms are placed towards the front with a large outpatients' visiting-hall of considerable length, divided into three bays, corresponding to the three consulting rooms behind, its principal entrance being from Francis-street. On the first floor the board, secretary, and medical superintendent have rooms in front, and behind a centre wing is thrown out for resident officers, sitting-rooms, &c. The next floor is occupied by the male special wards, skin and dental cases, ear and throat patients in front, and ophthalmic wards in the back wing; the lying-in department at the corner between it and residential college. The third floor is devoted to the female patients in the centre of main front, and the lying-in wards, &c.; the two upper floors being divided into cubicles for nurses. The architectural treatment of this design is conceived in quite a palatial style, massive and dignified in the line of its fenestration, cornices, and parapets, and more suited for a dressed stone façade than for brick. There is a curb roof, but no salient features to break the skyline of the main fronts. On the whole, the departments are well classified, and light and ventilation are studied.

The design "Sursum Corda" is characterised externally by a neatly-arranged front façade of brick and stone dressings, gabled at centre and at wings, five stories in height. The main entrance in Praed-street is central, with consulting-rooms right and left, and an out-patients' waiting-hall behind in connection with entrances for male and female patients in Francis-street. In the basement are drug stores; the secretarial department is on the first floor, where are also the special wards for lying-in cases. The second floor is mainly given up to bedrooms for the residential college, &c., and the next floor plan provides for the special wards for ear and throat, skin and dental cases, with nurses' cubicles in a wing at the back. The plan of wing resembles that of "Fleur de Lys" in its general shape or outline. The college in the Francis-street frontage forms the first return wing to the left, and is chiefly devoted to sitting and bedrooms; the special wards on the third-floor form the inter-

mediate portion of the letter **W** and face Praed-street, the centre projection at the back are the nurses' cubicles near main staircase, and the right-end block is the lying-in wards. The arrangement is wanting in classification, and the corridor and internal communications are defective in light. The separation of the departments, especially the out-patients from those indoors, is very necessary, and this separation ought to be accomplished without losing sight of easy and direct intercommunication for the surgical and medical staff, both in the new wing and between it and the main building. Lighting of corridors and cross-ventilation of wards are also conditions of good planning that ought not to be overlooked.

The site for the new wing, the foundation stone of which was to be laid this month, is now being cleared of the old and dilapidated houses which stood between the existing hospital and Praed-street, towards which the principal front will be. The present hospital of red brick, without any relief, is certainly an ugly and extremely heavy structure, which the new wing will, or ought to, do something to redeem.

THE LICENSING SESSIONS OF THE LONDON COUNTY COUNCIL.

ONCE more the caterers for public entertainment have thronged the sessions houses at Newington and Clerkenwell, applying to the Theatres and Music Halls Committee of the London County Council for the recommendation to the Council of the renewal of old, or the granting of new, licenses for music, dancing, and stage-plays. The interest taken in this annual meeting of the licensing authorities is not confined to the applicants only; the public at large watch with eager interest the decisions pronounced by the chairman of the committee. Many of the listeners are interested parties in a monetary sense, for now that music halls are run by limited liability companies, the refusal or granting of a license, means a considerable difference, one way or another, to the income of the shareholders, especially where such large dividends, as we read of, are paid.

No voice could speak louder of the growing tendency of the public taste for something, shall we say, lighter in the way of performances, than the fact that four well-known London theatres appeared in the list, as requiring music and dancing licenses from the Council, in lieu of the license already held by them for stage-plays, granted by the Lord Chamberlain. It is worthy of consideration how far a structure designed by an architect for one specific purpose, is a fit and proper building for a totally different usage. To our minds the requirements of a music hall are distinct from those of an opera house, or a house built for the drama, comedies, or comic operas. Each and all of these have their own peculiar requirements. In a music hall the audience is essentially a moving one; while in a theatre it is a stationary one. In the first, the people leave their seats, walk about, and return to them, or not, at will; while in the latter, they remain seated the whole time the curtain is up. The particular movements of the audience, must, therefore, require particular provisions on the part of the architect; and further, a moving and circulating audience will be of a greater number in any given theatre, than a seated assemblage in the same house; the question of the adequacy of the available exits is, therefore, one to be seriously considered, apart from the internal arrangements and fittings in converting a theatre into a music hall. It is not all a "question of smoke."

It is unnecessary to mention to our readers that this last question, is not one that is likely to be overlooked by the Theatres and Music Halls Committee of the Council;

we may all rest assured that that body exercises to the full the powers conferred on them by law, with regard to the provisions for the safety of the public; and were they not to do so, the public would cry out with a loud voice, that the men they had elected to look after their interest, safety, and welfare were neglecting the duties they had promised to perform, duties which are not only moral, but imposed upon them by various Acts of Parliament. One of our contemporaries appears to complain that: "the position of a lamp, the particular doors to which certain bolts are fixed, the determination of what is a gangway," should not be matters which affect the granting of a license. We contend that, if upon these matters, the safety of the public depends, the Council are but fulfilling their public duty in seeing that the defect are remedied. Small matters should not be overlooked, for they do "often carry with them very weighty consequences."

It is not our intention now to enter into a discussion upon structural matters, but we cannot help expressing our surprise at the number of places which still appear to be undergoing structural alterations. After the lesson, taught by the Theatres Committee in previous years, in refusing licenses where the works had not been carried out in the specified time, or in a manner to satisfy their superintending architect, it is a matter of wonder that applicants, who still had works to carry out, could allow the annual licensing day to approach, without completing the necessary alterations. On this score, it appears, the committee again stated that they would recommend the full Council to refuse certain licenses where the works were incomplete. This seems to us a matter requiring the architect's attention. The Council have declared that they will not grant a license unless the premises are complete to the satisfaction of their architect. It is, therefore, the duty of an architect to see that his client is armed with a certificate of the Council previous to appearing before the licensing body.

This applies with equal force to old applications, where works have to be done, as to new applications; for in the latter category, several licenses were refused, because the plans were not approved, and it is understood that the chairman of the bench, informed the applicants that as they had no certificate of the Council, they, the committee, were not entitled to grant a license; and in other cases they were told that their plans had been sent in too late to enable the Council to intimate to the applicants through their superintending architect, the defects shown in the drawings; and much too late for them to remedy the defects in the building, so as to bring it within the rules and regulations of the Council, in order to obtain the required certificate.

Here is another lesson for the architect who has clients requiring a music, dancing, or stage-play license of the L.C.C. Apply early: for this is certain, that it is necessary to ascertain in what way the structure, if it exists, or drawings, if the building is to be put up, must be amended, so as to comply with the rules and regulations of the Council. Apply early, so that when a notice has been served, or intimation given, as to what alterations are required, the works may be carried out and the certificate obtained under the Council's seal, before the licensing sessions.

Another class of cases before the committee were those where the owners have found their present premises too small for the requirements of their business, and they have determined to enlarge and alter the existing building to meet the demands of their patrons. These cases have been classed with others upon which the Council have served their notice for structural alterations, and the public press have ignorantly complained of requirements "practically en-

tailoring rebuilding" being imposed upon owners who are voluntarily altering their buildings. But whether the work be voluntary or not, the Council insist upon the due completion, while considering the renewal of the license; no alteration of any kind whatever is allowed without the previous consent of the Theatres Committee.

Turning to the legal aspect of this affair, the Council, as successors to the Metropolitan Board of Works, are, under the twelfth section of the Metropolitan Management and Building Acts Amendment Act, 1878, empowered "to make, alter, vary, and amend such regulations as they may think fit with respect to the requirements for the protection from fire" of places of public resort, to be kept open for the public performance of stage-plays and music and dancing. After the making of such regulations, the Act says: "It shall not be lawful for any person to have, or keep open, any such house, room, or other place of public resort for any of the purposes aforesaid, unless and until the Board (now the Council) grant to such person a certificate in writing under their seal to the effect that such house, room, or other place was on its completion, in accordance with the regulations made by the Board in pursuance of the provisions of this Act for the time being in force, and in so far as the same are applicable to such house or other place, and to the conditions (if any) annexed thereto by the Board.

"In case any such house, room, or place of public resort, is opened, or kept open, by any person for any of the purposes aforesaid, contrary to the provisions of this enactment, such persons shall be liable to a penalty not exceeding fifty pounds for every day on which such house or place of public resort is kept open as aforesaid."

From this it would appear, that, even, if it were possible, were a license granted to premises not holding a certificate, the owner would still be liable to the penalties mentioned in this section of the Act; for it is the non-holding of the certificate—not the license—which carries the penalty imposed here. The penalties of the licensing Acts are apart from this and do not concern the architect. It is certain that the architect must make his structure comply with the regulations, and that he must obtain the certificate before applying for the license. Applicants, with the law so clearly set forth before them, have only themselves to blame for the refusal of their licenses on the score of the unfitness of their buildings; if they ask in time, they can find out whether or not their premises can be altered so that they can obtain the desired certificate before the licensing day.

There is another point we must not pass over—that is, the power the Council have of granting provisional licenses under the thirteenth section of the same Act. It does not seem to be generally known that "a person interested in any premises about to be constructed, or in course of construction, which are designed to be licensed and used within the Metropolis for the public performance of stage-plays, or for public dancing, music, or other public entertainment of the like kind, may apply to the licensing authority for the grant of a provisional license in respect of such premises."

"The grant of such provisional license shall, in respect of the discretion of the licensing authority and procedure, be subject to the same conditions as those applicable to the grant of a like license which is not provisional. A provisional license so granted shall not be of any force until it has been confirmed by the licensing authority; but the licensing authority shall confirm the same on the production by the applicant of a certificate by the Board (now the Council) that the construction of the premises has been completed in accordance with the regulations and conditions made by the Board as herein-

before provided, and on being satisfied that no objection can be made to the character of the holder of such provisional license."

In new cases, therefore, the drawings should be passed by the Council before the work is commenced, and a promise should be obtained that the certificate shall be issued on the completion of the work in accordance with the approved drawings. Upon this, before spending any money on building, the applicant can go to the Licensing Committee and ask for a provisional license. He can, in fact, be secure of his license provided he carries out the plans, and is of good character, &c.

The majority of new applicants, however, at the recent sitting of the Theatres and Music Halls Committee, seemed to be those who had built first, and thought afterwards that they would like a license, or who had been frightened into a belief by recent police court convictions, that the business which they were carrying on at their premises was illegal without a license. Certain parties have been convicted and fined for keeping open certain houses, rooms, &c., because they had no certificate; this does not seem to have been at all clear in the minds of the applicants. It does not matter how good and fit a building may be, the rule applies: No certificate, no license.

Where a building has been licensed for some time, and the Council have required works to be done during the year, when such works are finished, it would appear that it is the custom of the Council to issue, what is known as, a certificate of completion, stating that the works have been done to their satisfaction. Our advice to architects is to have their plans approved and a provisional license obtained before commencing work; and where the building already exists, to make it comply with the Council's regulations, and obtain a certificate before applying at the October sessions, and, above all, to open their negotiations with the Council in time to do all the work (if any) required before licensing day of next year. Then there will be fewer disappointments and less heart-burning and expression of feeling in open court.

BEGINNING AT THE WRONG END.

A MIGHTY war of words has been going on in our hearing for the last year or two. "Is Architecture a Profession or an Art?" "Shall Fellows be still admitted to the Institute on the present system?" "Should examinations be compulsory on everyone who aspires to practise as an architect?" These, and others like them, are the matters that have been earnestly discussed; and, on the surface, some of them seem too unpractical for busy men to spend their time in talking about. What does it matter to them whether the business of their life is described as an art or a profession? Call it which they may, they will carry it on no worse and no better. Give some dull plodder the title of artist, and you will not make him one. Give some erratic genius the name of "professional adviser," and he will be no staidier than he was before. So it looks at the first glance. But in this war, as in many others, the real subjects in dispute are very different from, and very much more serious than, the nominal ones. The question which really divides the disputants seems at bottom to be this: "Can a man's faculty as an architect be truly gauged by any form of examination?" If it can, and if the required form of examination is really practicable, then, it would seem, there is not much left to dispute about. But to devise the examination is the difficulty. It is easy enough to ascertain by examination what statements a student has learned. Morning, noon, and night we are hearing all over the country of examinations like these—to believe in them is the great super-

stition of the age. But an examination as to actual capability is quite another thing. We may see, perhaps, its small beginnings here and there. They may die out, or they may grow and expand until we shall be able to test not merely what a man has read and remembered, but what practical work, artistic or other, it really lies in him to do. If we ever manage that we shall have an examination worth passing.

Examinations in capability, like those in learning, would, of course, be progressive. There would be an early and much-needed one, to ascertain whether an intending student was likely by any amount of training to be shaped into an architect. There would be intermediate ones, to see how the shaping was going on, and if the capability was being strengthened as it should be; and there would be advanced or final ones, in which the work that an architect actually had done should be the main thing to count, and in which the examination should only serve the purpose of a check, to prove that he had indeed done it himself. Each would have its appropriate tests of faculty, and our purpose now is only to suggest one among them. It would be too severe for the first examination, and too easy for the last; but in the intermediate it might be of great value. It turns on the fact that almost every plan—almost every design—almost every detail contains a problem; and it consists in ascertaining at what point, or at which end, the candidate would begin in attacking the particular one that happened to be set him.

By nature every student seems to begin at the wrong end. The pupil in his early years is irresistibly impelled to draw the elevation of his building before he has thought about its plan. He goes on the same principle in attempting details, and shows the lines of his arch-mould or his cornice before he settles the section of them. If he is dealing with a bay-window, he first of all sets up the outside of it, and fills in all the ornament; then he makes a section, carefully omitting the floor and ceiling lines; and lastly draws a plan. The interior he commonly omits entirely; and, of course, he does not concern himself with the sizes of casement frames or sash boxings. He has produced a neat drawing, and it is very difficult for him to understand that it is a worthless one. You put in for him the floor and ceiling line of the room which the bay belongs to, and it turns out at once to be too high or too low. You mark the walls of the room against his plan of the bay, and it proves, perhaps, to be too wide for the position. You set out the sash-boxing to a larger scale, and it takes up so much of the thickness of the wall that there is no room for the mouldings and the ornament which he began by showing. From end to end of his work there is scarcely a line which can remain, and when the rubbing-out process is complete, a deep disappointment settles down on the youthful aspirant. He had taken trouble, and had done his best; it does seem to him that you might have passed it, at least, with a few trifling alterations. Yet how was it possible? He had begun it all at the wrong end.

The young student has generally some knowledge of geometry. He would admit, in the abstract, that the greater cannot be contained in the less. To admit a truth and to act upon it, however, are two very different things, and his daily practice will flatly contradict the principle which his reason assures him must be true. It will not make him hesitate for a moment about putting a door 8ft. high into a passage which is only 7ft., or in placing three 4ft. windows and four 3ft. piers in the side of a room not more than 20ft. long. He will not deliberately assert that piers and windows making up 24ft. can be got in to a 20ft. space; but figures give him the headache, and addition and subtraction especially jar upon him, as inconsistent with the dignity of art. It takes

years, perhaps, to make him understand that the first necessity in every detail of a building is to let the detail fit into its place; that before designing a door or a window, it is indispensable to know what space there is for the door or the window to go into, and that all the different things he is drawing are not going to be worked and set up separately in a mason's yard as specimens, but will have to be fitted together to a nicety, so as to constitute a house, or a school, or a church. But for a long time he draws the things first, and ascertains afterwards how large they ought to be. In other words, for half his term of training, and it may be for the whole of it, he begins in this respect at the wrong end.

These are elementary examples of the mistake. But it is not confined to pupils; it is common enough with assistants; it is a characteristic of many practising architects throughout their lives. At one time or another, probably, it has been made by the ablest of men when they have found themselves dealing with unfamiliar subjects. Almost everyone learns in time at which end to begin his ordinary work. He comes to see at a glance which are the fixed factors and which are the movable ones, and he takes the fixed ones into account first. In a new class of building the difference is not equally clear to him. He is conscious of a terrible tangle, but he cannot for a long while discover the knot which holds it all together. Yet such a knot there generally is, and until it is found and untied all other trouble is thrown away. It is not always discoverable by sitting down and thinking. It may be better perhaps to take a pencil and a scale and begin somewhere—anywhere. Such a beginning will not lead to success, but it is likely to suggest, after a while, where the beginning will have to be. That once ascertained, it is possible to start again, to good purpose.

It is needless to remind anyone, except, perhaps, manufacturers of terracotta and moulded bricks, that buildings are, as a rule, begun at the foundations and gradually carried upwards. Firms in the branch of trade just named do sometimes seem to forget the prevailing custom, and, in consequence, deliver the finials and copings before they have made the plinths and bases; but to the rest of the world the practice is sufficiently familiar. Yet, though the execution of a building starts from the bottom, the design of it often originates at the top. This is especially the case in domed and vaulted buildings. The domes and vaults are thought of first, then the sizes and positions of the piers that carry them, and of the walls and buttresses that counteract their thrust. If the process were reversed, the buttresses and piers would be too weak or too heavy, and both would be in the wrong places. It is the same with other kinds of construction, as soon as they become difficult enough or massive enough to require special study. The right end to begin at is to calculate the weights that have to be carried, and then to design the supports for them; to ascertain the thrusts that have to be resisted, and to arrange the abutment accordingly. But the *crux* of a problem does not always lie in such easily-stated things as these. It may be hidden in the planning of a building, or in its section; in its internal or its external design, or in all of them combined. But wherever it is, there is not much to be done till one sees it and recognises it. It has to be tracked out and conquered—that is the end to begin at; and that once accomplished, secondary things generally fall into their right places with little trouble.

Not unfrequently the knotty point in a design is the lighting of the central part of it. The man who begins at the wrong end goes on admirably as long as he is working round the sides of the plan. His arrange-

ment looks satisfactory: his elevations please him; his drawings are getting on well. Then, just as he is hoping to complete a very promising scheme, he finds the middle of his structure in the dark. All he has done must be thrown aside; the labour of days or weeks must go for nothing; he has come at last on the difficulty of the problem, and must begin with it or give everything up. He sees now that it was with the lighting of the centre he ought to have started, and for want of having seen it, he has wasted his time and his trouble. Sometimes, again, the heart of the puzzle lies in getting proper communications across a building. Some way or passage is peremptorily needed at a particular point. It seems a small thing, and yet it cuts the site into two parts, neither of them large enough for the main apartment which has to be provided. Here the passage is clearly the fixed element which it is necessary to begin with. At other times a particular room has to be kept quiet and away from the noise of street traffic. To keep it so upsets some pet idea with which the planner started, and yet, unless he keeps it so, he loses his chance in the competition. Or it may be a question of aspect which predominates. The architect may have sketched out a house-plan, good in arrangement, and admitting of satisfactory architectural treatment. Yet when he sets it out on the actual site, he finds, perhaps, that it will make his most important rooms face the north, or will thrust their windows full on a prospect which would be absolutely intolerable. So he again learns, though rather late, which was the right end to begin at, and has good reason to regret that he began at the wrong one. Experience teaches us all, in these or similar ways, but it is he who acquires the lesson most rapidly that shows the most promise. To begin at the wrong end is not an absolute disqualification if a man has perseverance enough to do his work twice over. To begin at the right end is not all the mystery of our profession, but it is a considerable element in it, and the student who has an instinct for doing it gives a sign of capability which is likely to prevent him from ever becoming a conspicuous failure.

ARCHITECTURE: A PROFESSION OR AN ART.*

AS we were informed was the intention, the volume containing the protest published in the *Times* in March last year against examination and registration of architects, together with various short essays on the qualifications and training of architects, has been published by Mr. John Murray, under the editorship of Mr. R. Norman Shaw, R.A., and Mr. T. G. Jackson, A.R.A., the leading spirits of that movement. It would be impossible in a short article to deal as adequately as we should like with the arguments put forward by the writers against the legislative qualifications of architects. We have so often discussed, indeed, the *pros* and *cons* of the question that it would be superfluous to enter into the subject *ab initio*, or even to reassert all that we have already said in favour of a test of a general kind by which the public may be satisfied with the credentials of any architect they may employ—a test, it must be remembered, not whether he is an artist, but whether he is skilled in those elementary principles of construction and sanitary science as will entitle him to undertake the duties of carrying out any building entrusted to his call. Mr. Jackson, who writes the introduction, attacks first that movement which has instigated all the measures which have been proposed to improve the status and education of architects—namely, the Registration Bill. "Legislation," says Mr. Jackson, "has at last reached the domain of Art, and it has been seriously proposed to charge Parliament with the duty of providing the public with good architecture and properly qualified architects." This, the first sentence of the book, shows the main object the editors

have in view. The sentence we have quoted certainly misjudges the intention of the promoters of the Bill, which nowhere proposes to provide the public with good architecture or to make architects, but simply to insure the adequate instruction of everyone who practises the art in the essentials of good construction and the knowledge of all that contributes to safe and sanitary buildings. We accept the dictum that to a "true artist his art is an individual matter purely between himself and his artistic conscience," and that "no stamp of Government approval on his work can have any value in his eyes." It is perfectly true that any architect worthy of the name would never attach much value to a certificate of merit by a public board, knowing very well what it is worth; perfectly true that he must go his own way and his art must be free. We accept these statements; but they do not apply to the rank and file of those who now enter the profession, and for whom the public board's certificate may be the only guarantee to the ignorant, unsuspecting client. The reference to the arts of painting and sculpture are rather beside the main argument, for, as we say, no examination ever proposes to test the art capacity of the candidate. Mr. Jackson refers to jerry-building. No legislation, he says, could make it impossible, for so long as people insist on having too much for their money, so long will there be jerry-building. We are told that the jerry-builder would pass the examination with flying colours, for in his own way he is a master of construction, or rather how to make the most of a very little. The writer again says that the advocates of certificate and diploma do not think of trying to reform the jerry-builder, but to create a class of certified architects. Replying to the argument drawn from the certificated professions of the Bar or Medicine, we are told that it is not every qualification which admits of the examination test: even in law and physic it is no guarantee that a man will not bungle a case or diagnose wrongly. Lawyers have been known, "in spite of their diplomas, to draw wills which diverted property to the wrong recipient, and doctors to treat a patient for brain fever who was really suffering from inflammation of the lungs." But the chief thrusts are given at the Institute of British Architects.

Referring to Mr. MacVicar Anderson's threefold qualifications of the architect, one who unites the qualities of an artist, a constructor, and a man of business, Mr. Jackson observes justly enough that much of the latter qualification is very simple, and the rest is a matter of tact and experience, as in knowing how to certify for payment, what things ought to cost, &c. It is difficult to assure the public of anyone's qualifications on this head, and Mr. Jackson examines the test questions given to candidates in one of the examination papers of the R.I.B.A. on business qualifications, and shows how inadequate they are to guarantee his proficiency. Only four questions were to be answered, and two of these afforded no proof of one of the three essentials required by the president's definition of the architect. With these comments we leave Mr. Jackson's remarks to the attentive consideration of the profession, and refer to other essays by various writers which are intended to enforce the arguments against registration and diploma.

Mr. Norman Shaw, R.A., writes the first essay entitled "That an Artist is not necessarily Unpractical." He observes that "so far as the Institute of British Architects is concerned, it is too often felt that art is very much thrust into the background, and attention incessantly, and with much agitation of mind, kept concentrated on the 'profession' and the public." The general purport of Mr. Shaw's essay is to show that all the talk about practical knowledge and the diplomas of a qualified and chartered body is very "tradesmanlike and in very poor taste," and so far as the public is concerned absolutely untrue; that the public want good architecture which will interest them, and will be a daily source of delight. In short, that the public, when they employ an architect, are not content with sound construction, but look for art, that they will never be put off with certified surveyors, or officially made architects, however many letters they may have to their names. Mr. Shaw says if an architect designs a really "interesting" work, he will be sought after. "To build beautifully" is the main object of an architect; "if he sits in his office making picturesque

drawings, he may be an accomplished draughtsman, but he is not an architect: if he spends his time in calculating the smallest amount of material that may be used, he may be an engineer and builder, but he is not an architect. Mr. Shaw does not undervalue "business" qualifications when they are valuable to the employer, but a man's "aptitude for business can only be discovered in business," and cannot be ascertained by examination. Mr. Shaw believes that an architect must be endowed by nature with a special gift for the art, and if he has no art faculty, he may, with a very little industry, attain to skill in construction and details; he maintains, in short, that good construction is a part of good architecture, and must influence design, and all great architects have been men of great practical attainments. "A true architect is more likely to be a practical man than a practical man is likely to be an architect." Lastly, Mr. Shaw admonishes the student "to put away all empty talk about the 'profession' and the public," to give up all anxiety to have initials after his name.

The second essay, by Mr. J. T. Micklethwaite, F.S.A., on "Architecture and Construction," is an important contribution, because it shows how very mundane and practical is the Institute's ideal of an architect. The quotation from Professor Kerr's book, the "Consulting Architect," about the different kinds of so-called architects, reads certainly like an irony. Mr. Micklethwaite points to the strange doctrine that there may be professional architects who have no knowledge of architecture, and he shows that such a doctrine has obtained in Conduit-street, for both Professor Kerr and Mr. MacVicar Anderson have included under the term architect a great variety of mixed callings. The root of this misconception is, as he shows, the idea that architecture "is ornament applied to building," a luxury that may be added to or "laid on" if you choose to pay for it. As to the claim of the Institute as really representing the architects of Great Britain, he says it is "too shallow to be maintained." Alluding to the threefold division of architects, the writer says truly there is plenty of honest work for a business architect to do; he may be a house agent, or land-jobber, but has no claim to the title of architect. "If there is a slaughterhouse or a coal-store to be built, and there is a man who knows exactly what is wanted, and how it may best be had, by all means let him have the work to do, but do not call him architect—a 'prosaic building director with Professor Kerr,' if you like, but not an architect." Speaking of the artist qualification, the writer says construction is a necessary condition of architectural design; architecture being building beautifully, it is, in the first place, building. Stress is laid on the fact that architecture is not overlaying building with ornament, but is a quality inherent in a building; that the work of the architect is not the drawing of pictures, but the designing of buildings.

After a paper by Mr. Reginald Blomfield, M.A., on the "Institute Examination and Architecture," the remarks on the inaptitude of examination tests, and on designs submitted by examinees to examiners in the following essay by Mr. G. F. Bodley, A.R.A., are very much to the point, and worth perusal. The other essays, by Mr. Mervyn Macartney, B.A., on "The Protection of the Public," and on "Architects and Surveyors," by Mr. Ernest Newton, are in the same general keynote. Mr. Edward S. Prior, M.A., writes a clever essay on "The Ghosts of the Profession," which contains some unpalatable truths for professional architects. Mr. Prior remarks: "Some architects have not run in the professional ruts, but have disregarded the emoluments which reward the conventional professional success . . . but these have not generally been successful men. Their names are not found in histories of modern architecture, even when re-edited. . . . Indeed, many of the real architects of this century have not been accounted at all." Much more in this strain may be found in other essays. Mr. John R. Clayton writes on "The Isolation of Professional Architecture from the Arts"—a subject we lately discussed in these columns, and this isolation has been fostered by the Institute. Mr. Basil Champneys, B.A., has an able essay on "The Proper Relation of General to Technical Education"; W. R. Lethaby one on "The Builder's Art and the Craftsman"; W. B. Richmond, A.R.A., on "Thoughts on Three Arts and the Training for

* "Architecture: A Profession or an Art." Edited by R. NORMAN SHAW, R.A., and T. G. JACKSON, A.R.A. London: John Murray.

them"; Gerald C. Horsley on "The Unity of Art," and Mr. T. G. Jackson's concluding essay on "True and False Ideals on the Education of an Architect," to which essays we can only refer. The tone of them is high; the authors counsel the profession to think more of architecture and less of the profit and position of the architect; everyone rebukes the Institute for its pandering to the commercial side and not doing more as an institution of architecture. As to the question of examination, it is looked upon in much the same manner as journalists in this country regard the course of journalism which has been established in the University of Chicago.

ARCHITECTURAL ANTIQUITIES OF THE ISLE OF WIGHT.

[WITH LITHOGRAPHIC ILLUSTRATIONS.]

THE concluding part of Mr. Percy G. Stone's admirable work issued to subscribers under the above title has now been published. The present volume comprises the Domestic work of the West Medine, and naturally enough the Royal Castle of Carisbrooke occupies the most conspicuous place in length of description and number of illustrations. These latter include some specially prepared photographs and measured plans with geometrical details of all the parts retaining points of architectural interest. The chapel of St. Peter is carefully restored by Mr. Percy Stone in plate 124. The history of the fortress is amplified with copious notes, bringing its record down to the present time, and noting, by the way, Hardwick's over-restoration of the fabric in 1856. Chale Manor, a small farmhouse with walls and windows of 14th-century date, is one of the most interesting domestic buildings in the island, and was erected by John de Langford, Constable of Carisbrooke Castle, in the days of Edward III. There is also an interesting barn with buttresses to the walls, as in the well-known Somersetshire examples, and possessed of at least one old original principal of the roof. Cowes Castle, Kingston Manor, and Mottistoun come next in order in the book. Of the latter, by the author's permit, we give herewith, among our plates to-day, a plan, view, and elevation. The house stands on the high road from Ventnor to Freshwater, and was the ancient home of the Glamorgans and the Chekes. One of the latter family, "a lewde sonn of a discrete fathor," sold the property to Sir Robert Dillington, of Knighton, whose descendant, Sir Tristram, sold it again to John Leigh, of North Court. The house dates from the first part of the 16th century. The main body of the house was probably remodelled about 1567, the date cut in a panel over the entrance porch. The eastern wing was presumably relegated to the servants' use as domestic offices. Nearly all the internal door openings are of stone, with flat-arched lintel heads and splayed and stopped jambs, but the house is sadly out of repair. Newport furnishes some picturesque bits of work, and the grammar school is an unambitious and quaint building. North Court, of which we are enabled to give a view, is perhaps the most stately manor-house in the Isle of Wight. It is pleasantly situated on the south-eastern slope of the down overlooking the sea. It never seems to have been of the conventional Jacobean type of manor-house, but appears to have been modelled more on the lines of the more important mansions to be found on the main land. The entrance front has been retrievably metamorphosed by the insertion of ash windows, but the garden side is much as when it was built. Over the porch is cut the coat of arms of the Leighs, argent, on a chief embattled sable, three plates, with the date 1615. The south and east fronts are picturesquely roken with angle-canted bays of two stories, unmounted, like the gables, with quaintly elaborate finials. The view of the house from the south-east angle is an imposing one, gaining much from its foreground of formal garden and the little stream that here runs through the grounds.

Among the smaller specimens of historic domestic architecture brought before us by Mr. Percy Stone are Shalcombe, Simerston, and Rowbrough. Sheat is a bigger place, with a grand chimney-piece in the dining-room, and Swainston is a pretty little chapel and hall. West Court and Wolverton are good small houses, and Lymington is made the most of by Mr. Downes's artistic, but almost too magazine-like,

sketches. So conclude the plates, which number 146 full pages, besides numberless marginal illustrations. The volume concludes with historical references and quotations both on the churches as well as houses of the West Medine, which cannot fail to be of interest to the local antiquarian, and they must have been the occasion of much patient research among many curious authorities giving customs and manners of bygone times. In an appendix form are inventories of church-plate and chattels, with an account added of the alien priories in the island. The printing both of the plates and letterpress is excellent, and the work has been published by the author at his offices in Great Marlborough-street, W.

ROAD AND FOOTWAY BLOCKS.

WE have never desisted from finding fault with those systems of road-paving which appear to be made for the very object of causing a slippery surface and of making it difficult for horses to keep their feet. In spite of continual warnings, little has been done in this direction; but we are glad to call attention to the road and footway blocks which the Patent Composite Block Road and Paving Company, Ltd., of East-side, Newport, Mon., has introduced. Mr. William White, the inventor of the Hygeian Rock and managing director, has, we believe, been for a long time engaged in perfecting the system, which combines the merits of asphalt and macadam without those drawbacks which have generally been discovered in their application to roads. A roadway combining the qualities of durability, cleanliness, and good foothold has been called for in all great towns. Authorities in London and elsewhere have tried all kinds of pavings of macadam, of wood, and of asphalt, but they have not yet succeeded, simply because the condition of foothold has been neglected. The patent composite block is of any required shape or size; small granite cubes are imbedded in a layer of composition made of asphalt and other materials, and these layers are attached to blocks or slabs of cement concrete. The blocks are, by means of dovetailed apertures, made to unite with the composition or base. The granite cubes inserted in the composition make an excellent foothold. Two varieties of paving blocks are manufactured. First, blocks prepared with a base of the best cement concrete, and faced with a layer of impermeable composition, which firmly adheres to the concrete base, and is also keyed to it by means of dovetailed apertures, and on the wearing surface are imbedded pieces of road metal broken to any required size. These blocks can be made of any thickness, shape, and dimensions. The surface may be ridged, grooved, or plain, or to any desired pattern. Secondly, blocks prepared with the same composition, but without the base of concrete, with a framed grating or gridiron of timber imbedded therein. These can also be cast to any size, shape, or pattern. For heavy traffic the second class of block is recommended, 6in. thick, having a weight of 392lb. a square yard. For light traffic, blocks of the first kind are preferred, and these have already been tested. Their cost is rather less than those entirely of composition, but their weight is 576lb. to the square yard. For passenger traffic either kind would suit, or a block of concrete 2in. thick, faced with a $\frac{3}{4}$ in. layer of composition. For stables, cattle markets, and other purposes grooved blocks of 2 $\frac{1}{2}$ in. to 3in., as shown, would be suitable. One great advantage of these blocks is the rapidity with which they can be laid on concrete foundations, and the facility with which repairs or openings of the roads for drains and pipes can be made by simply cutting out the groove or joint, and removing the blocks. The results of experiments made to find the resistance to bending stress of these blocks made by David Kirkaldy & Son are instructive, and prove the remarkable strength possessed by the composite slabs.

THE LONDON COUNTY COUNCIL AS THEIR OWN CONTRACTORS.

THE London County Council discussed, on Tuesday, the long-mooted proposal that they should in future do their own building work without the intervention of a contractor. The question arose on the report of the Bridges Committee with regard to the proposed erection

of artisans' dwellings for housing the persons displaced by the making of approaches to the Blackwall Tunnel. The committee reported that the Council had referred to them the several tenders for the erection of artisans' dwellings on the Yabsley-street site. On further consideration they thought that it would be more economical if the Council were to erect the buildings; by so doing they would save the extra cost which would be represented by the contractor's profit, and also the expense of supervising the work. The Council, moreover, could rely upon having the best materials and workmanship, and at the same price that would be charged in the first instance to contractors. They therefore recommended—"That the Council do erect the artisans' dwellings to be constructed in connection with the Blackwall Tunnel scheme, without the intervention of a contractor, and that the Public Health Committee be authorised to take the necessary steps for carrying out the recommendation." In the discussion which ensued, Mr. John Burns, M.P., and Mr. J. Williams Benn, M.P., strongly supported the recommendation of the committee, and advocated that the County Council should carry out the whole of the building operations. Mr. Burns stated that for four years he had consistently advocated the Council having a distinct building department and a committee of works. He denied that those who supplied contractors with plant would not sell to the London County Council, and read a letter which had been received from an eminent firm offering them material on advantageous terms. Sir J. Lubbock, M.P., warned the Council against embarking on this step without further inquiry, and proposed an amendment instructing the committee to reconsider the whole question. This and other amendments were negatived, and the committee's recommendation as far as the word "contractor"—viz., the motion to proceed with artisans' dwellings—was carried, with an instruction to the committee to report as to the best manner in which such works could be carried out in future.

THEATRES.—X.

By ERNEST A. E. WOODROW, A.R.I.B.A.

IT has often occurred to me, that sufficient stress is not always laid upon the importance of the arrangements for the admission of the public into a theatre. All of us, who have been frequenters of the pit of some of the popular playhouses, must admit that we have had some very uncomfortable quarters of an hour—or even whole hours—in waiting for the doors to open, and when they did open this discomfort was brought to a climax. I have elsewhere endeavoured to point out that much of the nervousness among women, and those of a highly-strung temperament, is due to the disgraceful way in which the British public have been in the habit of struggling and fighting into the pit and gallery of our theatres. Where great difficulties are felt in obtaining access to the seats, the idea of an equal, or greater, difficulty of gaining egress, is nursed by the weaker minds during the whole of the performance, destroying all sense of enjoyment, and creating a state of nervous excitement, ready to burst into a cry of alarm at the slightest cause. It requires but the voice of one over-wrought person to start the whole audience into a mad stampede, fire or no fire; on the other hand, it requires but the presence of mind of the whole audience to secure a safe departure, however fierce the fire, and however well founded the alarm. The lesson that our security is in our own hands cannot be taught too often.

What I would now dwell upon, is this—that the plans made by the architect for the admission of the public, should be such, as to prevent all overcrowding, and allow the most delicate and sensitive woman or child to walk into a pit or gallery without any discomfort or feeling of fear. This can be done, and in several of our new theatres has been, and is being done; the way to do it has been learned from our Continental neighbours. Who could imagine a Parisian audience behaving like a Boxing Night crowd? It needs a certain amount of moral courage to enter Drury Lane gallery on the first night of the annual pantomime, and, the public have themselves greatly to blame.

It seems almost impossible to teach the public, that the way they have behaved in the past is not the right way; so means must be provided to prevent future recurrence of the disgraceful scenes witnessed nightly at the pit and gallery

doors—scenes of greediness and selfishness which Englishmen should be ashamed of—where the strongest thrust the weakest to the wall, to gain a front seat. First to come should be first served in a theatre, and it is only by the architect arranging his entrances so that the “queue” must be enforced, that this will be brought about. Managers are quickly learning the lesson taught them by Mr. D'Oyly Carte, some years since at the Savoy Theatre, that a large portion of the public who cannot afford high-priced seats, keep

FIG. 1.

away from the theatre altogether, because of the discomfort of the entrances to the “unbooked” parts. Mr. D'Oyly Carte was the first to adopt the “queue” to his pit, and now it is no uncommon sight to see ladies standing outside and quietly awaiting admission to the Savoy pit in Beaufort-buildings whenever there is a *matinée*. This example has since been followed by many managers, and, as I have already mentioned, special arrangements have been made in some new theatres by the architects to carry out the system.

We all remember how the queue was formed by a series of barriers to the lifts of the Eiffel Tower at the last great Paris Exhibition. Such an arrangement worked well with the vast crowds in the open air; but were it adopted in the entrance passage-way of a theatre, which has also to serve as an exit, it would materially obstruct the free egress, and be a cause of very great danger. The exit must remain free at all times, and no system of shifting or movable barriers should be allowed in order to overcome the difficulty. Some modified form of the plan shown in Fig. 1 is frequently adopted, by which the public enter and pass the pay-box one by one in a narrow passage; after the pay-box is reached, the stream diverges into

FIG. 2.

the main passage-way, which is left free and unobstructed, its full width, for the purposes of exit. Such an arrangement works admirably. The people can wait in a line in the street under the shelter of a permanent awning; the bolt of the small entrance door at A can be released by the money-taker pulling a lever from the pay-box, and the audience walk quietly in one by one, knowing that no amount of struggling will permit them to pass those in front, or gain a superior seat in the theatre. Several variations of this system are adaptable to the various exigencies of different cases.

In Figs. 2 and 3 a plan is shown where the entrance passage has a turn at right angles. Here the people enter and pass the pay-box, as in Fig. 2, where the letter A indicates a barrier kept in position by an automatic bolt or fastening on the inside; as they go out, this barrier falls back by simple pressure in the position shown in Fig. 3. B is a door to close the space before the pay-box in case anyone when

FIG. 3.

going out should be pushed aside, and be unable to again enter the stream; this door folds back against the wall of the passage when the audience enters.

Everyone knows that the public have to be brought past the pay-box one by one, and when the pay-box is situated in the main entrance passage-way, the width of the passage-way must be curtailed in some manner, so as to bring the people singly up to the money-taker, otherwise a rush past the pay-box will fill the house with *dead-heads*. Ingenious and complicated provisions of check barriers have been the result of the demand of such circumstances, arrangements which were not always conducive to public safety. The necessity of the presence of barriers, in order to govern the ingress of the people, appears to be recognised by the London County Council, who in a part of their twenty-fifth regulation say that “all barriers and internal doors shall be made to open outwards, with no other fastenings than automatic bolts.” Again, “no locks, monkey-tail, flush or barrel-bolts, or locking-bars, or other obstructions to exit shall be used on any doors, gates, or barriers.”

Barriers should be hung to open outwards, and not have any fastening, so that should a crowd suddenly turn round and rush out before the commencement of the performance, the barriers would give way before them, and fall back against the walls, leaving a free exit. Barriers that have to be lifted out of sockets and carried away, are a great evil; there should be no unshipping or unfastening in any case.

I cannot find anything in foreign regulations to guide us as to what provision is enforced with regard to barriers in other countries. The necessity of the barriers and of their opening outwards has called forth the inventive faculties of managers, and I here illustrate an arrangement patented by Mr. Graydon, from a drawing he has supplied me. It will be seen that

FIG. 5.

one end of the barrier is held against the wall, and travels in a runner, while the centre and other end are hinged. The drawing shows that inward pressure will keep the barriers in such a position that there is only room for one to pass the check-taker at a time, and that directly outward pressure is applied the full width of the passage-way is available. This system is specially useful, where long barriers are required, to bring a crowd gradually to one point. Where a barrier is longer than the passage is wide, it is, of course, impossible to hang it to swing outwards without blocking the passage-way. Mr. Graydon's patent appears to solve this difficulty.

In Fig. 5 I illustrate a very simple method (invented by a “gas-man” of one of the East-end theatres) for holding a check barrier in position without any fastening which would cause an obstruction to an outgoing crowd. A rod (A) of iron or brass, which is hooked into the barrier, is

FIG. 6.

placed into a tube or pipe (B); this is attached to the wall (at C). When the barrier is pushed outwards the rod comes out of the tube, extending like a telescope (as at D), the barrier falls back against the wall into a recess formed so as not to diminish the width of exit; the barrier may be kept in this position by a spring or self-locking latch.

We have already learned that all doors should

FIG. 4.

open outwards. The twenty-fifth rule of the Council, however, reminds us in the following words that it will not do to open a door outwards into the face of a waiting crowd:—

"All doors used for entrances, and all gates, shall be made to open both ways, and shall, when opened inwards, be locked back against the wall in such a manner as to require a key to release them."

Any one who has experienced, as I have, the opening of a pit door, on a first night in a new provincial theatre, will easily understand the wisdom of this provision; it would be dangerous—indeed, simply impossible—to open a door *into* a crowd. When the door is opened, the above rule provides that it must be secured against the wall, so that it cannot sway about among the crowd.

The pay-box should be a permanent part of the building; temporary and movable arrangements are dangerous, apt, as they are, to be upset by an out-rushing crowd. They obstruct passages and corridors, and diminish the size of the vestibules. It is advisable to place the pay-box as far away as possible from the entrance door, to permit the people, who are waiting admission, to stand under cover in the passages and staircases. It is in the arrangement of such details as pay-boxes, that the architect can provide, for the management, a theatre which can be worked nightly at a reasonable expense. Some theatres, it is well known, are much more profitable to run than others, because their internal arrangements

are such, as to require but few attendants to issue the tickets, collect the checks, and show the audience to their seats. Having this in view, pay-boxes can be so planned as to permit two or more pay-windows to open into two or more entrance passages and staircases; by this means one attendant clerk can collect the money for more than one division of the audience, saving the weekly salary of one man. Especially is this practicable where one section of the audience is admitted a few minutes before the other, for example, so as to get the rush of the gallery over before the rush of the pit commences.

Fig. 6 is the outline of an arrangement whereby two sections of the audience, A and B, can take tickets at one pay-box, but at two windows, P P. The barrier shown at A is as placed for entrance, while at B it is thrown back for exit. Even where the rush is too great for one clerk to attend to both windows, there is still an advantage in having two or more pay-boxes in one, as the acting manager has an easier task in supervising the money-taking department—an important one in a theatrical enterprise. Where possible the pay-boxes should be placed in connection with, or near to, the treasury office, for obvious reasons, this being the centre governing this department.

It has been truly remarked that too frequently the box-office, where the day booking is carried on, has the appearance of being an afterthought, placed as it is in out-of-the-way corners. A vast amount of business is done nowadays in forward booking—so much, indeed, that at some theatres

queue barriers are placed during the day in the vestibules, leading the patrons of the house one by one to the box-keeper, and his model or plan of the numbered seats in the theatre. The box-office should be an office of respectable size, not a dark hole or cupboard, or a wooden structure, resembling a sentinel-box introduced into the vestibule, suggesting that its need was not thought of till a short time before the theatre was opened to the public. Communication by telephone or speaking-tubes, and lift for the conveyance of letters and parcels, should be provided between the box-office and the manager's room. As a rule, this office is the inquiry office of the theatre, and any one having business with the managers first apply to the box-office keeper.

After the people have been admitted, paid their money, and received their checks or tickets, they, before reaching their seats, have to give up their tickets to attendants. This is a matter of management, which as far as the booked parts of the house are concerned need not trouble the architect, a staff of programme attendants usually meeting the demand; but with regard to the cheaper parts of the house the case is different, for any one who "rushed" the pay-box might get a seat without paying, unless a further barrier and attendant stopped their progress. Therefore at the end of the passage-ways, or at the top of the staircases leading into the auditorium, a barrier must be placed, which will allow of only one person passing at a time, and permit the check-taker to collect the tickets that have been pur-

chased at the pay-box. Such a barrier is shewn in Fig. 5.

These barriers should be without fastening, and hung so as to swing outwards back against the walls, where a strong self-locking latch or spring should hold them in position. The pressure of a crowd passing inwards will keep them in position when in use without a fastening. On a staircase they can be made to open against the riser of a step, in a passage against a flap or stop, rising in the floor, which will fall flush with the floor when the barrier folds back against the wall. A similar stop can be provided in the ceiling where barriers are used of a height from floor to ceiling. A bar of the telescope pattern above described is also admissible, or a chain from the well to the barrier, which will be in tension as the crowd press inwards, and fall loose as they pass out.

The check-taker is usually provided with a tall, narrow box, with a slit in the top, into which he drops the tickets as he takes them. This box is locked, and is taken by him after all are admitted into the treasury, where it is unfastened, the tickets counted, and checked against the money handed in by the clerk from the pay-box. Now, it would at first sight seem to be no business of the architect to worry himself about such a trifle as this ticket-collecting box, yet it is a fact that in one of the well-known catastrophes in theatres in this country a staircase was blocked through the fall of a person over one of these boxes—others fell over him, and many deaths were caused by this apparently simple cause. Permanent provision should be made for these boxes; they should not be moveable, but, as in the case in a London theatre, be built flush into the wall.

TWYFORD'S "DELUGE ADAMANT."

MR. T. W. TWYFORD, the well-known sanitary potter of Hanley, Staffordshire, has introduced a wash-down pedestal closet basin, that for solidity and strength has few compeers. The speciality known as the "Deluge Adamant" is made in extra strong Cliffe Vale fireclay, enamelled inside and out, made in one piece, the thinnest part being more than one inch in thickness. It is, therefore, practically unbreakable, and is admirably suited for schools, factories, workhouses, asylums, barracks, and for all places where there is rough usage and where strength and good flushing are required. The basin has an S-trap, and the water surface

basin and trap, the improved flushing arrangements, and the large surface of water, together with the deep-water seal, ought to be sufficient to recommend it to all architects who are specifying closet fittings for public buildings.

DYKE CONSTRUCTION IN HOLLAND.

A VERY instructive account is given of the Holland Dykes in a paper by W. Starling, M. Am. Soc. C. E., in the *Transactions* of that society. The system of modern dyke construction dates back to the 13th and 14th centuries. In 1421 a storm carried away the sea-dykes, destroyed 72 towns and villages, inundated 200,000 acres of land, and drowned half that number of people. This inundation (St. Elizabeth's Flood) gave a new conformation to the Lower Rhine and Maas, and created a great swamp that has since been only partly reclaimed. The writer distinguishes three kinds of dykes—sea-dykes, river-dykes, and internal dykes. The first are built with great strength to stand the shock of heavy seas with a very long slope, one of the best safeguards against heavy breakers. Even a sea-beach slope of 40 or 50 to 1 is given, though it is not practicable to give so flat a slope as this usually. The front of dyke is protected by stone. The dykes for safety sometimes have to be 18 ft. or 20 ft. higher than mean flood. The western shores of the Zuider Zee are less exposed to storms than those of the North Sea, and the dykes are reduced in size accordingly, though even the smaller ones are heavier than required to stand the mere head of water. Some of the first-class dykes, according to Mr. Caland, the Dutch engineer, on the North Sea have steep banks, perpendicular to the direction of the westerly winds, a crown of, at least, 4 metres, a front slope of 10 to 1, a little convex, with the lower portion somewhat steeper, about 6 to 1—protected by heavy stone pitching. Of the second class on inland rivers the crowns are about 3.5 metres, and the front slope 6 to 1. Of those less exposed, the crowns are about 2 to 2.5 metres, and the front slopes of 3 or 4 to 1. All these dykes have a back or land slope of, at least, 2 to 1, an inner berm or banquette of 4 to 10 metres, and another berm somewhat sloping in profile carried up 1 or 2 ft. above flood tide. These dimensions have been increased of late years, according to Mr. Starling, who gives some useful details and sections of the *hoofden* or pile dykes, consisting of two or four rows of piles, pro-

struction, and describes the modes of protection by tarpaulins, the damages to which dykes are exposed, the causes of disaster, leakage through or under the dykes, weak foundations by ice gorges, &c. The plates illustrate outline sections of numerous dykes on the Lek, Waal, Linge, &c.

IRON ARCHES OF LARGE SPAN.—III.

CAST IRON.

IN the first examples of the employment of cast iron to arched ribs in France, on which subject very little information exists, the engineers there showed a much greater regard for theory than their English *confrères*. Practically, however, their early cross-sections were inferior to those adopted in this country, as an inspection of Figs. 5 and 6 will at once indicate. These figures represent the cross-sections adopted in the cast-iron arched ribs of the Pont du Carrousel, and of a similar structure at Corbeil. It is obvious that both of these sections may be regarded as consisting of two semi-elliptical portions, bolted together at top and bottom, thus forming each an entire elliptically-shaped tube. In a former article on this subject, we drew attention to the great and universally-recognised advantage of the use of cast iron in this particular class of bridge design, inasmuch as it permits of a comparatively large amount of material or mass of metal being concentrated in one thickness, and constituting what may be termed an integral cross-section of rib. This important advantage of employing the material *en masse* is, to a great extent, if not altogether, lost in the sections in Figs. 5 and 6.

It may be put forward against this statement, that, as an arched rib is altogether, or, at least, very nearly so, in compression, the drilling of the holes and the use of bolts for connecting together the two half-sections—for such each really is—does not weaken the form adopted. If the material were wrought iron, and rivets were used instead of bolts, then, on the assumption that the latter completely filled the holes, and that the iron was only subjected to strains of compression, the argument might hold. It has been found that, where pins have been substituted for rivets in railway bridges, the incessant jar and vibration caused by heavy passing trains, ultimately causes them to loosen. The Cramlin Viaduct, which has spans of 150 ft.—a very moderate dimension for a structure of wrought iron—became so "shaky" under similar conditions, that rivets and gusset pieces, and other measures had to be resorted to, in order to place the bridge in a state of security. Whatever doubt may exist in either of the two instances alluded to, we do not think that any can exist with respect to the two-halved sections under consideration. If the arched rib is called upon, as some authorities assert, to act as an ordinary girder under transverse strain, the bolts would unquestionably be liable to a shearing stress, and their area and strength must be adapted to resist it. It should be mentioned here, in fairness, that the employment of this particular design of arched ribs may have resulted from necessity, and not from choice. The capabilities of the French foundries at the time these castings were made may not have been equal to turning out such large masses of metal in one solid piece. The depth of each cross-section in Figs. 5 and 6 is 3.3 ft., and in these days would probably have been considered a "large" casting.

A consideration of the "moment of inertia" of the two elliptical cross-sections, as well as of the manner in which the material is generally distributed, will corroborate our opening statement in the present article. Neither of the sections have any breadth in the form of flanges any more than the plank-on-edge example alluded to in Article I., but in the present instance the absence of any value for b is, to some extent, compensated for by the removal of the material from the central vertical axis of the figure, and concentrating it at the sides of the tube. If we make T the semi-transverse axis, and C the semi-conjugate axis, and I the moment of inertia, as before, we obtain

$$I = \pi \times C T^3. \text{ Should } C = T \text{ then } I = \frac{\pi T^4}{4},$$

which is its value for a circular section when $T = R$, the form into which the elliptical section would become converted under those conditions. The other limit of C will be $C = 0$, in which case the value for I also equals zero; but

in basin is 7 in. by 5 in. The section of this combination-trap and basin is well adapted to insure self-cleaning, as there are no angles in any part. The basin has a spherical bottom, forming part of the siphon, and the inlet and upper lip insure a good flush. The price for closet, yellow enamelled outside and white inside is 36s., and the basin can be fitted with a 3-gallon national siphon cistern painted or galvanized. This pedestal form has many advantages over the old style of closet, as it can be made ornamental, can be kept clean, and is free from all casings of wood which harbour dust and dirt. Twyford's "Deluge Combined Washdown Pedestal," with earthenware or lead trap, S or P-shaped, fitted with or without slop-top, is another form of sanitary closet worth notice. The formation of

jecting 6 ft. or so, driven about 6 in. or 8 in. apart, between which on each side of the rows is a carefully laid bed of clay, brush, and stone, the latter about 2 ft. square. The sea slope is about 23 to 1, the steeper slope being next the shore. The rows of piles are strengthened by waling pieces on both sides, and the *hoofd* is divided into sections by cross piles and heavy horizontal ties. The straw mat or *krammat*, consists of a thin layer of carefully-selected straw, cramped by ties or binders of the same material, placed at short intervals, and pressed into the earth by a two-pronged fork. Its use is to form a kind of footing to keep the heavier material, bricks, &c., from sinking deeply and irregularly. Often this matting decays; the slopes are firm, dry, and hard. The author mentions other forms of con-

if instead of reaching the actual vanishing limit of the semi-conjugate axis, we make C very small, then the sides of the sections tend to approach each other, and we revert to the form shown in Fig. 1, which was the original cross section for cast-iron arched ribs in this country. The total absence of any value for " b " in the rib in Fig. 5, was evidently considered a defect by French engineers, as in the subsequent example in Fig. 6 it was endeavoured to be remedied, although to a very trifling degree, by the modification shown in the upper and lower portions of the cross section. Had the tubes been cast in one piece, the alteration might have been attended with some corresponding advantage; but as the width at these points does not exceed 4in., and the tube is divided into vertical segments at the centre of the width, the enlarged portions are in themselves devoid of continuity, and therefore fulfil properly the functions neither of a flange nor top and bottom of the tubular section. Longer distance pieces require to be inserted between the "ears" or "lugs" of the rib, so that it is very questionable whether, practically, the arrangement in Fig. 6 is any improvement upon that adopted in Fig. 5, in which the two halves of the section are "coupled up" in a firmer and more compact manner. Both these forms of cast-iron arched ribs are stiffer than those we have brought under review; or perhaps it would be more correct to say that they would be stiffer if they were integral sections, and were not obliged to rely upon bolts and nuts for a great part of their resistance and stability.

The general features of the half-elevation of one of the ribs of the "Pont du Carrousel" are shown in Fig. 7. The span is 160ft., and the arch is segmental in form, struck from a radius of 325ft. Putting R for the radius, C for the semi-chord, and V for the rise or versed sine, the value of V is easily obtained by solving the equation $V^2 - 2RV = -C^2$, and will be found equal to 10ft. It may be mentioned here that a cast-iron arch bridge, of very nearly the same span as that described, was built at St. Petersburg over the tideless river Neva nearly sixty years ago. This bridge consists of seven arches, of which the centre one is built in eleven segments, and has a span of 156ft. Although the dimensions of the relative spans of the two structures are approximately identical, the resemblance does not extend to their respective "rises." The value for V in the Russian example is 14'3in., or nearly 50 per cent. more than in the case of the French bridge. By increasing the radius the arch becomes "flatter," and more headway can in this manner be obtained at and near the springings; but this advantage is gained at the cost of an increased horizontal thrust against the abutments. Where additional or extra headway is required beyond what is afforded by a properly proportioned segmental arch, it is preferable to adopt an elliptical or parabolic profile. The ellipse, however, under all conditions, gives more headway at these particular points than the parabola. Westminster Bridge, the arches of which are, in the central part, of wrought iron, and of cast at the haunches or springings, is a fine illustration of this especial curvilinear contour. It may, nevertheless, be stated that there are practical objections to this felicitous combination of cast and wrought iron in one and the same design.

There is one element in the half-arch in Fig. 7 which deserves attention in all similar structures, as it is of considerable importance, and may affect, to some extent, the actual nature of the

stresses brought to bear upon the rib itself. We allude to the shape adopted for the spandrels, which generally may be classed under one of three classes. They may be continuous, like the web of a plate girder; diagonal and open, similar to a lattice-girder web; or vertical and insistent. In the last instance they resemble the vertical suspending rods of a suspension bridge with the tension stresses changed to others of compression. The spandrels in Fig. 7 are composed of circular rings, and on the supposition that they touched the rib and the upper horizontal stringer only in one point, they would practically belong to the third or last class. In defending the design, the author commented upon the advantage accruing from the use of this particular form of spandrel, inasmuch as they deflected slightly under a passing load, and so transmitted it to the rib without any impactive force or jar. No doubt they may sometimes act in this satisfactory manner; but as a matter of fact, they are far more liable to break, and so cause the destruction of the arch. Instances of such fractures are on record; but we must reserve for another article further information and existing examples relating to this interesting and instructive detail of cast-iron arch buildings.

OBITUARY.

HERR GEORGE BLEIBTREU, the celebrated German battle painter, died at Berlin on Sunday, aged 65. He was born at Xanten in 1828, commenced his art studies at Dusseldorf Academy at the age of 15, and subsequently worked under Theodor Hildebrandt. On the outbreak of the Franco-Prussian War of 1870-71, Herr Bleibtreu accompanied the headquarters staff of the then Crown Prince of Prussia at his Royal Highness's special invitation, and accompanied the German forces to Versailles, where he established a studio. It was here that he painted many works representing incidents in the war.

At the Sheffield Police-court on Monday, Walter Gosling, builder, was summoned for not obtaining the necessary permission from the borough surveyor to fix up hoardings where he was erecting houses in Woodburn-road, Attercliffe. Through not having fixed up some hoardings a young woman fell into the cellar of one of the houses, and sustained serious injuries. He was fined £2.

The parish church of Weston, near Bath, has been enlarged at an expense of about £4,000, by the building of a north transept, a south transept, and an extension of the east end. The whole of the church is to be reset. Mr. Harbottle, of Exeter, is the architect, and Messrs. Stevens and Bastow, of Bristol, the contractors. The cornerstone of the new work was laid on Tuesday, by Mrs. Frazer, widow of the Bishop of Manchester.

Two new chapels of the monastic church at Downside, near Bath, have been opened. They are situated in the north aisle of the chancel, and adjoin the chapel of the Holy Angels. The one next to that chapel is dedicated to St. Placid. The details of the reredos have been copied from paneling in Selby Abbey, and those of the altar from arcading in Canterbury Cathedral. The carving is by Mr. Wall, of Cheltenham. The window represents scenes from the life of St. Placid, and has been designed and executed by Messrs. Hardman, of Birmingham. The glass of the second chapel, the chapel of the Seven Dolours, is also from the same firm. The flooring of both chapels is the work of the Rust Mosaic Company, of Bristol, and is from designs by Messrs. Dunn and Hansom, the architects of the church.

COMPETITIONS.

BRAMLEY, NEAR LEEDS.—In the limited competition for the new Liberal Club at Bramley the designs of Messrs. Jowett Kendall and J. Harper Bakes, M.S.A., architects, of Leeds and Idle, have been accepted by the directors.

INFECTIOUS HOSPITAL, KEIGHLEY.—Thirty sets of drawings were sent in for the above competition, and the approved and accepted plans were submitted under motto "Isolation" (No. 2), by Messrs. Judson and Moore, Keighley and Bradford. The first premium has been awarded to the plans under motto "Progress," by Messrs. Marshall and Dick, 13, Grey-street, Newcastle-on-Tyne; the second premium to Mr. W. de Lacy Ahern, C.E., 55, Colmore-row, Birmingham, under motto "Ab Wortha."

CHIPS.

A new pier for Weston-super-Mare has been resolved upon, and the necessary Parliamentary powers will be applied for. The structure will be longer than the well-known one at Southend, being 2,200yds. in length and 16ft. wide, whilst the pier-head will be 160ft. by 50ft. On the pier will be formed twelve shelters, and concert-rooms will be erected at the pier-head.

Good progress is being made with the works for a supply of water to Oundle, now being carried out by the local board of that town. Mr. Radford is the engineer, Messrs. Siddons and Freeman are the general contractors, and Messrs. Cochrane and Co., of Dudley, are supplying the pipes.

Last week the foundation-stones were laid of a Congregational church in Pearl-street, Saltburn-by-the-Sea, in the presence of a large company. The building is to be in the 14th century style, with a tower and turret in Pearl-street, and will have seating accommodation for 303 persons. Mr. Caleb Petch, of Scarborough, is the architect, and the cost will be £1,400.

A new branch bank was opened at Grantham last week. The contractors were Messrs. Herbert, of Leicester.

The Salford Corporation having been asked whether it is willing to advance a sum of money to the Manchester Ship Canal Company towards the cost of completing the canal, the council determined on Wednesday to view with favour a proposal to advance the company £1,000,000, provided the council secure adequate representation on the directorate, and are able to raise a loan on favourable terms.

The death occurred last week, at Hereford, of Mr. William Bowers, a prominent builder and contractor in that city, who died from pulmonary disease at the age of 63 years.

Mr. James Reckitt has offered to present to Hall a library, valued at £5,000, and an income of £300 per annum, contingent upon the town adopting the Free Libraries Act.

Workmen are at present engaged near the Stephenson Monument, Newcastle-on-Tyne, preparing the way for a drinking-fountain which will shortly be erected on that spot. The fountain is to be erected by the trustees of the late Mrs. Burn, a daughter of Newcastle's great builder, the late Richard Grainger, the site having been granted by the Town Improvement Committee for the purpose. Constructed of grey and red granite, the fountain will have four faces, and in addition to the usual drinking cups there will be drinking troughs. The erection, which will be about 9ft. high, is of the dome type, and is crowned with a finial. The work is to be carried out by the Elswick Court Marble Works Company, Northumberland-street, Newcastle.

The memorial stone of a new Congregational church and Sunday-school at Staple-hill, Bristol, was laid on Wednesday. Plans for the church and schools have been prepared by Mr. Frank Wills, of Bristol, and the estimated cost of the scheme in its entirety will be £4,000; but it is proposed for the present to erect school premises only, consisting of a large hall, seating about 300 persons, a room for infants, and six classrooms. The estimated cost of this section of the scheme is £1,600.

The first ordinary meeting of the Session 1892-93 of the Surveyors' Institution will be held on Monday, Nov. 14, when the president, Mr. Charles J. Shoppee, will deliver an opening address.

The Derbyshire County Council have authorised a committee to take legal proceedings against the corporations of Derby and Burton-on-Trent, to compel them to cease polluting the rivers Derwent and Trent respectively. Burton has a sewage farm; but it is alleged that the sewage runs from it into the Trent. The Derby sewage is turned direct into the Derwent.

WAYSIDE NOTES.

I HAVE seen the great work, but as yet have had no time to peruse its contents. It is, I am informed, partly a re-hash of old letters to the *Times*, contributed by the authors who entered the list of combatants in the recent Quixotic tournament among architects that took place in the columns of that journal. If this is really so, it is to be regretted. The generally neat and modest exterior of the book leads one to the conclusion that the contents are fresh and original. "Here," thought I, "is a book for a nook, with the comfortable adjuncts of pipe, slippers, and winter fireside." Warmed-up dishes, however, are not to my taste, either of palate or intellect. Neither do we incline to a great number and variety of courses, and would have preferred Mr. Norman Shaw or Mr. Jackson to the end of the chapter, in place of a hotch-potch of miscellaneous opinions.

In the immediate future I shall hope to read the book. It is rather a pity that among the writers of the thirteen essays not enough ingenuity was forthcoming to invent a more suitable title than this old, threadbare, double-faced, disingenuous one: "Architecture—a Profession or an Art?" Most of us are well sick of the sight of it, and had hoped that it was comfortably dead and buried long ago. Apparently the only straightforward thing about it is the certain indication of the re-hash aforementioned.

I see I was in error as to the order of precedence of "art" and "profession" in the title adopted when writing last week. From the point of view of the writers, the order observed is the most suitable, and avoids an awkwardness of sound that otherwise occurs. There was also, by the bye, a printer's error in my first note last week. "Compared with the correctness of the workers" should have been "compared with the earnestness of the workers." Mr. Ruskin's argument was that laws of composition are mere vanity if the building is erected with a machine-like indifference to the work done—an undeniable position.

I suppose that now that the question of examination *v.* non-examination—for this, after all, is the essence of the matter—is to come to the front again, we shall have more washing of professional "dirty linen" in the columns of the public Press—things hateful to contemplate. We had enough of it before, goodness knows! All the possible—and impossible—faults of the architect, whether on the side of examination or of non-examination, were drawn in glowing pictures with apparent delight in the task. Anything less to the credit of any profession—or art, I beg pardon—whether divinity, law, medicine, or otherwise, it is not possible to conceive. If this is all coming over again, then, in my small way, I beg to remain on neutral ground. Time was when architecture and culture and refinement were substantives bearing due relation one to the other. What has come to pass during the last few years may have modified this. I do not assert, but put forward the suggestion. At such a time we may well think the more highly of those architects—elderly men for the most part—who have withheld from the wrangle in the public arena, and who have won, and continue to win and hold, the esteem and regard of patrons of architecture, even though they lack the cleverness of the smart school of design and the presumption of modern, acrobatic draughtsmanship.

Those who follow the doings of the British School at Athens will be interested in its annual report just issued. A special appeal for funds to continue the excavations at Megalopolis is made. The sum of £300—little enough for undertakings of this nature—is required to complete works commenced and to clear out the Thersillion—a building of much interest. A full report of discoveries so far made is to be issued by the Hellenic Society. The Thersillion will be known to classical readers, who may remember the allusion made by Pausanias to the building, as a council-house, taking its name from its founder. The place is described as being "an enormous rectangular hall, whose floor sloped from the centre to the sides, and whose roof was supported by row after row of columns in a very peculiar disposition, radiating from the centre as well as parallel to the sides." Mr. Ernest Gardner, the

director of the school, says that the difficulty attending the discovery at Megalopolis partly results from a complicated relationship between the theatre and the Thersillion, the great portico between the two buildings serving, in a peculiar manner, as an integral part of both buildings. The full report of the Hellenic Society will be anticipated with much interest by enthusiastic archaeologists. The hon. treasurer of the British School at Athens is Mr. Walter Leaf, of Old Change, who will receive any subscriptions to the works of excavation.

Colonel Hughes' allusion to the School Board at Tuesday's meeting of the County Council can scarcely be said to have been happy. There has been bad building, certainly; but the evil came about rather because the officials of the Board neglected their duties or were expected to do more than they could accomplish in the way of overseeing, than because the Board put the work out to contract. Private architects manage easily enough to get work done by contract as satisfactorily as possible, and why cannot school boards and county councils? Now, the County Council intend to try their hands at being master-builders. The Council propose to build some artisans' dwellings, rendered necessary by the clearances for the Blackwall Tunnel, and, in spite of many antagonistic opinions, have practically resolved to do without any contractor, and trust to their own officials and such others as, it is presumed, they will temporarily engage, to get the building erected. The avowed object is the saving of money. Whether this end will be served is very doubtful. It may be very good to do away with contracts for artistic and architectural motives; but an inexperienced Council is not much to pitch against a contractor whose whole training and experience tend to and facilitate economical working expenses, and whose wisdom is chiefly the knowledge of cheap markets. The County Council puts too many irons in the fire at one time. At any rate, they might openly avow that interest in the working classes induces them to take certain views; when, the benefiting of working men being uppermost, and the protection from "sweating" paramount, we might fall into ideas similar to those of the good Councillors.

I hear that the building now just commencing on a site next Sion College on the Thames Embankment is to be *sui generis*. Report has it that the work is in Mr. Pearson's hands; that the owners are from across the Atlantic; and that the instructions have been to "crowd on all sail," to use a figurative expression—in other words, the architect may spend any money to produce his effects. Jacobean is in the air as the style, and untold granite glories are to be a feature.

The remains of Her Majesty's Theatre, as I saw them a few days ago, have something of the massiveness of a Roman ruin. The vast thickness of walls, the great openings of proscenium arch, &c., and the nature of the material—brickwork of the simplest order—all help the effect. The theatre appears almost vaster in its dismantled, wrecked state, than when densely packed with people, and with all its hangings and decorations. It looked big enough then.

Except in case of a leak caused by knocking a hole in the side of a vessel or other unforeseen occurrence, steamships of to-day ought to be proof against their fires being drowned out. There is something more than usually tragic and impressive in the end of the P. and O. steamer *Bokhara*. The non-nautical mind can scarcely grasp the full significance of the telegraphic despatch: "The sea ran mountains high, repeatedly sweeping the decks, and finally extinguishing the engine-room fires." The *Bokhara* was built on the Clyde in '73; but I should imagine that ships can be so designed and constructed at the present day that it would be practically impossible for any seas sweeping their decks to penetrate in sufficient quantity to cause any serious danger in the stoke-holes. The prevention of a disaster such as that which overtook the ill-fated ship in the China seas, would, one would think, be the first care of naval architects.

GOTH.

The name of Charles Richard Gurr, of Maygrove-road, West Hampstead, builder, appears in Tuesday's list of adjudications in bankruptcy.

Engineering Notes.

RAILWAY WIDENINGS NEAR BICKLEY.—Since the opening of their new route via Catford and Peckham from Bickley to St. Paul's, the London, Chatham, and Dover Company have commenced an extension of their railway lines at Shortlands and Bickley. Commencing at Shortlands Junction, and running as far as the bridge over the line at Woodlands-road, Bickley, a distance of 2 miles 133 chains, a double pair of lines is to be laid, along which the local passenger traffic will be carried. Messrs. Lucas and Aird, the contractors, have begun the work of laying the rails, and the relative changes in the railway system which this measure entails. Foremost among these are the building of new railway stations at Shortlands, Bromley, and Bickley. At Shortlands the present station-house will be demolished, and a new structure will be put up. The present bridge will be widened from 25ft. to 40ft., and will be constructed of iron girders resting on massive brick abutments. A subway will be taken through under the railway, 82ft. from the old bridge, leading to two island platforms. On the outer lines will be the up and down local trains, while the present lines will be utilised for through traffic. From the bridge there will run for 800ft. a heavy retaining wall towards Queen's Mead. At Bromley again the station will be shifted up on to the present bridge, which will be widened as to admit of a courtyard, and a new goods yard will be constructed. All along the route of the extension the line will be widened, additions being made to culverts, bridges, and cuttings. Bickley station will be treated in similar fashion to Bromley station. These works, which are estimated to cost at least half a million sterling, will be completed in ten months.

HIGHLAND RAILWAY EXTENSION.—The directors of the Highland Railway Company have received tenders for the construction of the last section of the through line from Inverness to Aviemore. This contract extends from the ticket platform at Millburn, near Inverness, through the estate and battlefield of Culloden, and over the river Nairn by a viaduct of 570yds. in length and from 58ft. to 129ft. in height. The successful offerer was Mr. John Mackay, the contractor for the Thurso Harbour extension works, who has already made several portions of the Highland line between Forres and Perth. The contract price for the new works is £117,925, the company, in addition, providing the permanent way material and fencing. The directors also accepted the offer of Mr. George Pirie, who has just completed the Burghhead and Hopeman extension, for the construction of the new branch to Fochabers. The amount of the contract is £8,960. The directors also resolved to ask Parliament in the ensuing session for powers to extend the present Dingwall and Skye line from the present terminus at Strone Ferry to Kyleakin, a distance of some ten miles.

MATLOCK.—The cable tramway, which is to facilitate communication up the precipitous hill between Matlock Bridge and Matlock Bank, has just been completed, when the consulting engineer made his inspection, and a trial car was run. The undertaking has been promoted by Mr. George Newnes, M.P., and the capital employed amounted to £20,000. Not only is the hill precipitous, by reason of which the gradient is 1 in 7 in Rutland-street, and varying lower from 1 in 7 to 1 in 15, but there are numerous curves. The route starts at the Crown-square, at the Bridge, and passing up Bank-road, crosses Smedley-street, and so on through Rutland-street to the tramway terminus, near Wellington-street, attaining in its half-mile course an elevation of 600ft. above the valley of the river Derwent. The terminal buildings have cost about £3,000, the contractors being Messrs. Knowles and Sons, of Matlock Bank. The laying of the tramway was let to Messrs. Dick, Kerr, and Co., of London. The work was commenced in April last, and it has been carried out under the direction of Mr. Croydon Marks, C.E., of Birmingham, at a cost of about £10,000.

The Dorset-gardens Wesleyan Chapel, Brighton, was reopened last Sunday after undergoing the process of extensive works of decoration, and formation of increased means of egress and of ventilation, and the electric light installation, the whole from the designs and under the superintendence of Mr. Arthur Loader, architect, of Brighton.

ILLUSTRATIONS.

ALL SOULS' CHAPEL, INVERGOWRIE, N.B.—TUBINGEN, WÜRTTEMBERG.—HIGHER GRADE SCHOOLS AT CHEETHAM.—BUSINESS PREMISES, CHESTER.—INTERIOR DECORATION, BY W. HENSMAN.—NORTH COURT.—MAUSOLEUM AT SEATON DELAVAL HALL, NORTHUMBERLAND.

Our Illustrations.

ALL SOULS' CHAPEL, INVERGOWRIE.

This chapel is being erected by Lady Frances Kinnaird as a memorial to the late Lord Kinnaird. It is built of Corsehill stone, the interior being likewise stone-faced. The roof is of open timber construction, covered with pale grey Westmorland slates. The spire, carried over the intersection of nave and transepts, is entirely of stone, and reaches a total height of 140ft. Mr. Hippolyte J. Blanc, A.R.S.A., is the architect.

THE MARKET-PLACE, TUBINGEN.

TUBINGEN is the university town of Württemberg. The old town-hall, of which we publish this week a sketch by Mr. Seth-Smith, forms one side of the "platz," generally described in the guide-books as part of "the irregularly built and unattractive old town," the fact being that outside this now limited area there is nothing worthy of a sketch; but within it many a boldly picturesque feature—such as the gateway to the castle, or a great dormer window of several stories in height—which compels one to sit down and study it. This "platz" is quaint and interesting, with every building in it set at a different angle, but producing a *tout-ensemble* extraordinarily picturesque.

CITY OF MANCHESTER SCHOOL BOARD—HIGHER GRADE SCHOOL, CHEETHAM.

This design was recently selected in competition; it is intended to be a mixed school for 500 boys and girls, and will be erected in Heath-place, Cheetham Hill, Manchester. The basement contains cellars for coal, wood, gas and water meters, kitchen, boiler, &c. On the ground floor is a gymnasium, 65ft. by 32ft. 6in.; two cloak rooms, manual instruction-room, 49ft. by 32ft.; a store-room, teachers' room, and two covered playgrounds, all with a clear height of 15ft. The first floor contains boys' and girls' (mixed) department—viz., six class-rooms, each 25ft. by 25ft.; two class-rooms, each 27ft. 6in. by 25ft. 6in.; master's room, with ante-room; also a teachers' room, with store-room and two cloak-rooms, the above (excepting teachers' room) to be 15ft. high in the clear. The second floor is divided into cookery-room, two science-rooms, each 25ft. by 25ft.; a chemical laboratory, 61ft. by 24ft. 6in.; balance-room, store-room, the whole having an average height of 17ft. On this floor is arranged an excellent drawing-room, 66ft. by 25ft. 6in., average height 19ft., with two good cloak-room and a teachers' room. This art school has a good north light. Care has been taken to provide good entrances and staircases, the girls entering at the eastern and the boys at the western end of the building. The ground-

floor corridors lead direct to the gymnasium and playgrounds. An auxiliary staircase is provided at the rear of the building, providing access from the playgrounds to the upper floor and to each department; this will be found serviceable in emergencies. There are two open playgrounds and two covered playgrounds for boys and girls respectively. The usual offices are provided. The entire school will be warmed by large, open fireplaces of the best pattern. Ventilation by hopper sheets and extraction flues is provided throughout, special chambers, &c., being arranged for the chemical laboratory. Internally, the walls of the ground floor will be pointed and dis-tempered. On the upper floors glazed tile dados, 4ft. high and with with plastering over, will be used. The staircase walls will be lined with glazed bricks, with suitable dados. Generally, the building will be of common brickwork, with stock dressings; the masonry will be of Rain-hill stone, with landings, &c., of Yorkshire stone from Greenmoor quarries. Wood-block flooring will be laid on concrete beds in some portions and pitch-pine flooring boards in others. Playground floors will be concreted. The roof timbers will be of red deal. Internal joiners' work of pitch-pine, and the roofs covered with Welsh slates, with Ruabon ridge tiles, &c. The style adopted is Flemish, of a Gothic type. The architects are Messrs. Royle and Bennett, of 17, Cooper-street, Manchester.

BUSINESS PREMISES, EASTGATE-STREET, CHESTER.

THESE premises are being built for Messrs. Dicksons, the well-known seed merchants and nurserymen. The architect has adopted the half-timber style of architecture, which is characteristic of the city, the woodwork being of oak, supported upon moulded piers and elliptical arches of polished red Aberdeen granite, which, on account of its durability, the architect considers a favourable innovation to the local freestone generally used. The building is of fireproof construction, the ironwork and floors being supplied by Messrs. Homan and Rodgers, of London and Manchester, and the whole of the work is being carried out by Mr. William Parrott, builder, from the plans and under the superintendence of Mr. C. A. Ewing, architect, both of Chester. Messrs. Whitehead and Sons, of Aberdeen, supplied the granite work.

INTERIOR DECORATION.

A DARK grey-green pattern, outlined with pale red on a golden ground, with blues, white, orange, and black in small portions, forms the filling of the wall spaces. The frieze consists of similar colours, but more numerous and varied. The ceiling depends for its effect entirely upon the decoration, being flat, and without any visible constructional features. A general warm tone, blue and yellow stars, dark grey and yellow corners to the octagons, and warm and dark grey, with yellows and broken orange tones, in the long panels, form the scheme of colour; the whole being paler in tone than the walls. The dado is very simply treated with light and dark tones of grey, with the mouldings here and there of the colours used in the filling over. The work was designed by Mr. Walter Hensman.

ARCHITECTURAL ANTIQUITIES OF THE ISLE OF WIGHT.

(See description on page 555.)

MAUSOLEUM AT SEATON DELAVAL HALL, NORTHUMBERLAND.

THIS mausoleum, an illustration of which appears on another page, is situated in the park at Seaton Delaval, not far from the Hall, which was built in 1707 for Admiral Delaval by Sir John Vanbrugh, the architect of Blenheim. It was erected by Sir John and Lady Hussey Delaval to their only son John, who died in 1775. It is covered by a leaden cupola, and approached through a Doric portico, each column of which is formed of a single stone. The interior is in the form of a chapel having a nave in the middle, with an altar or communion-table. Above this is a dome supported by semi-circular arches, and beneath are vaults. The mausoleum, however, has never been used for the purpose originally intended.—J. BRYSON RENTON.

New voluntary schools in Lock-lane, Allerton, Bywater, were opened by the Bishop of Ripon on Friday. The cost has been £1,500, and Mr. R. McDonald was the architect.

ARCHITECTURAL & ARCHAEOLOGICAL SOCIETIES.

SOCIETY OF ARCHITECTS.—The members' dinner of the Society of Architects will be held this year on November 15, at the Holborn Restaurant, at 7.30 p.m. Mr. Robert Walker, the President, will take the chair.

PRESTON MASTER BUILDERS' ASSOCIATION.—The third annual meeting of this association was held at the Castle Hotel, on Thursday evening in last week, the president, Mr. John Walmsley, in the chair. The secretary, Mr. John Tomlison, read the report for the past half-year, which stated that the number of firms on the books was 53, a membership which compared very favourably with any local association in the country. The death of Mr. Robert Park, vice-president, was referred to. The committee reported that the contract form adopted by the association was becoming more generally used. On the motion of Mr. R. Croasdale, seconded by Mr. Dewhurst, the report was adopted. Mr. John Walmsley was re-elected president, Mr. C. Walker, vice-president, and T. H. Kellett was elected a vice-president in the place of the late Mr. Park. Mr. R. Croasdale (hon. treasurer), and Messrs. Cottam and J. Cartmell (hon. auditors) were re-elected for the ensuing year.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.—The inaugural meeting of the session 1892-3 of this society was held at the Cutlers' Hall, Sheffield, on the 11th inst. A large number of members attended. The President, Mr. C. J. Innocent, delivered an inaugural address, in the course of which he congratulated the society on the satisfactory financial position in which it found itself, having a balance in hand. Referring to the proposed commencement of a class for the study by younger members of art, he mentioned that the idea was suggested by himself at last year's meeting. The idea was taken up by Mr. Gibbs, who read a paper on "Architectural Education in Sheffield." Mr. Gibbs was then requested to prepare a scheme. This had since been under the consideration of the council. This summer the younger members had been invited to form sketching parties, and many of them had visited the churches and halls in the surrounding district on Saturday afternoons. The scheme had worked very well. Arrangements had been made for a class during the coming winter, to be held at the school of art, and in direct connection with the society. At the close of Mr. Innocent's address, a discussion was taken part in by Messrs. Macdougall, Hadfield, J. B. Mitchell-Withers, and E. M. Gibbs. Afterwards a programme of song was gone through, with Mr. J. A. Podgers as accompanist, and the proceedings concluded with a form of conversation and a walk through the rooms devoted to the exhibits of the Society of Artists.

CHIPS.

The ceremony of laying the foundation-stone of the new Sunday schools and parish room for St. Mary Steps, Exeter, took place on the 13th inst. Mr. E. G. Warren is the hon. architect, and the contractor Mr. G. L. Stile, whose tender was accepted at £787. The large room is 54ft. by 26ft. in the clear, and will afford accommodation for 180 scholars. The class-rooms will be formed by means of revolving shutters. The building is being constructed of red brick.

The will of Mr. John William Grover, M.Inst.C.E., F.S.A., late of 15, Victoria-street, Westminster, and Chase Lodge, Clapham Common, who died on August 23, has been proved, the value of the personal estate exceeding £40,000.

Windsor-place U.P. church, Portobello, N.B., which was erected a dozen years since, was reopened on Sunday after the completion of internal decorations carried out by Mr. D. J. Tough, of Edinburgh.

The Lincolnshire County Council considered at their last meeting 46 applications for the offices of district surveyor as proposed to be appointed—one for North Holland and the other for South—under the new scheme resolved upon for the maintenance of new roads. Mr. Lewis Starkie, till now surveyor to the local board of Rothwell, near Leeds, was appointed for North Holland division, and Mr. J. W. Shaw, district surveyor to the Norfolk County Council, was appointed for South Holland. The value of the offices is £150 a year each.

The ratepayers of Colwyn Bay have decided to purchase, at a cost of £8,000, 42 acres of the magnificent Pwlycrochan Woods, to be free to the public for ever.

STATUES, MEMORIALS, &c.

OUTLON, STAFFS.—A monument has this week been erected over the vault of the late Mr. George Meakin, of Creswell Hall, in Outlon churchyard. It consists of four white Sicilian marble bases full of moulded and carved work, carried by a white marble ledger 9ft. long by 5ft. wide, and surmounted by 14 polished red granite columns and pilasters, with moulded and carved marble bases and caps. From these spring six moulded arches, carrying an overhanging canopy having two finials. Lying underneath the canopy, and between the columns, is a large moulded and bevelled inscription top, bearing an inscription. About 20 tons of white Carrara marble have been used in the work. It has been designed and executed under the personal supervision of Mr. James Beresford, of Belper. The memorial work also includes an alabaster tablet, which has been affixed to the inside of the church. The tablet is of Gothic design, and is the handiwork of Messrs. Jones and Willis, of Birmingham. On each side of the inscription, which occupies the centre of the tablet, is a niche, with carved canopy and pedestal. The inscription is overhung by a connected series of five canopies of elaborately carved tracery. The centre canopy is slightly larger than the others, and, passing through the square upper edge of the tablet, terminates in a pinnacle surmounted by a small cross. The niches are filled with figures of angels.

CHIPS.

The new public washing-house, constructed for the Edinburgh Corporation in South Gray's close, off the High-street, is approaching completion. The buildings have cost £3,800, and have been carried out from plans by Mr. T. Morham, the city superintendent of works.

At the last meeting of the town council of Birkenhead, Mr. T. C. Thorburn, C.E., tendered his resignation as borough surveyor and engineer, which was accepted, and he was appointed by the council to the position of consulting engineer to the corporation, at a salary of £250 per annum.

An alabaster tablet, 5ft. long by 2ft. broad, was completed on Wednesday by Messrs. Williams and Clay, sculptors, Warrington, and will shortly be erected in Hawarden churchyard by Mr. and Mrs. Gladstone, in memory of their eldest son.

A stained-glass window has been placed in the south aisle of Patterham Church, the work of Messrs. Burlison and Grylls, of London. The window contains three lights. Next to this window is another, containing two lights, filled in with subjects representing the four miracles of our Lord, and by the same artists. Both are memorials of the late Col. Wight Boycott.

Mr. E. H. Tulloch, A.M.I.C.E., commissioner under the Local Government Board, held an inquiry at the town-hall, Luton, on Tuesday week, relative to the proposal of the corporation to borrow £5,500 for the purchase of the premises adjoining the town-hall. The borough surveyor, Mr. T. R. Roscoe, explained that it was proposed to acquire the property for the enlargement of the municipal offices.

In the Oddfellows' Hall, Edinburgh, the second annual *soirée* and concert under the auspices of the local branch of the Scottish National Federation of House and Ship Painters was held on Friday night. Mr. Thomas Bonnar presided.

The twenty-third annual competition and exhibition in turnery, under the auspices of the master (Sir Richmond Cotton) and the court of the Turners' Company, will take place at the Mansion House on Wednesday, Thursday, and Friday next, the 26th, 27th, and 28th inst. On the last-mentioned day the Lord Mayor will distribute the prizes.

The parish church of Peebles has just been enriched by two stained-glass windows. The two windows are of two lights each, and have been treated as one work, there being represented the figures of the four Evangelists, one in each light. The artists are Messrs. Cottier and Co., of London.

A bust of the late Right Hon. W. H. Smith, in Carrara marble, has just been placed in the Guildhall (having been executed by Mr. J. Whitehead, of St. Vincent-square, Westminster).

A new Board School in Iydale-road, Nunhead, was formally opened on Wednesday week by Mr. Diggle, M.A., the chairman of the London School Board, who, in his opening remarks, stated that the site had cost the Board £5,000, including legal expenses, while the building, which was capable of accommodating 1,200 children, had cost £23,300.

The monument which is part of the memorial to the late Bishop of Durham was unveiled yesterday (Thursday) by the Lord Lieutenant of the county, Earl Durham. The cenotaph is from the designs of Mr. C. Hodgson Fowler, F.S.A. The effigy, which was commenced by the late Sir Edgar Boehm, R.A., has been completed by Mr. Gilbert, A.R.A.

WATER SUPPLY AND SANITARY MATTERS.

NORTON, NORTH RIDING.—The Norton Board of Health have borrowed £3,000, at 3½ per cent. interest, for the purpose of constructing an entirely new scheme of water supply. At present the town takes its supply from Malton, but the board were not satisfied with the arrangement nor the prices charged. The engineers of the new scheme are Messrs. Fairbank, of Driffield and Westminster, and it is to be in full operation by March 25th next. Already the contracts are let, and the work has commenced. The source of the new supply is a spring on the Howe Hill estate, close by the Malton steep-chase course, and a lease has been obtained on low terms for 100 years. The reservoir itself is being constructed out of the Howe Hill—a massive rock-bed of oolitic limestone—and the pumping-engine and well will be placed at the foot of the hill. The water will have to be pumped about three-quarters of a mile to the town, and for this purpose a six-horse gas-engine is being erected, with automatic apparatus for self-stopping immediately the reservoir is full. The contracts are in different hands. That for the laying of the main, &c. (£650), has been taken by Mr. Firth, of Scarborough, and Mr. Bell, of Market Weighton, has undertaken the construction of the reservoir (£1,200). The storage capacity of the reservoir (area 110ft. by 33ft.) will be 250,000 gallons. The Norton Board of Health have appointed Mr. Millington, of Driffield, as their clerk of the works.

WIRKSWORTH.—The local board of Wirksworth recently invited Mr. T. S. McCallum, of Manchester, and Mr. W. H. Radford, of Nottingham, to advise them as to the best method of sewerage the district. These engineers each prepared a scheme, both of which were considered by the board in May last. There was a great similarity in the schemes for sewerage, but the engineers were at issue as to the disposal and purification of the sewage when collected. Mr. Radford recommended purification by means of lime in tanks, followed by filtration through land. Mr. McCallum was against the use of lime, and strongly in favour of adopting the international system of purification by means of ferrozene and polarite. The difference in the cost was about £300. At a meeting on Wednesday week a vote was taken on the rival schemes, which resulted in Mr. McCallum receiving seven votes and Mr. Radford one. It was decided to ask Mr. McCallum to meet the board in consultation at an early date.

Progress is being made with the construction of the new fixed bridge for the Bristol corporation by Mr. A. Krauss, the contractor. The first of the voussoirs was laid on Monday, and before long the arch will be completed. The facing of the bridge will be of blue Pennant stone, with Red Wilderness stone quoins and mouldings. The arch stones will also be of Red Wilderness material, and the pilasters will be of similar stone, connected by an ornamental iron railing. The construction of the new quay wall is nearly completed. On the other side of the bridge, the culvert which will carry the waters of the From into the Floating Harbour is also progressing.

Lady Stewart laid, on Friday, the foundation-stone of a new parish church at Grantully as a memorial to her late husband, Sir A. Douglas Stewart of Grantully, Bart. The church, which is in the Gothic style, and which is being erected from plans prepared by Mr. W. Ball, C.E., of Aberfeldy, is to accommodate a congregation of 200. It is close by the site of the old church, and occupies a commanding position on the banks of the Tay halfway between Grantully and Aberfeldy. The edifice is 74ft. by 26ft. 6in. The interior is to be fitted up with pitch-pine, with open-timbered roof. It is built of hard native whinstone, the hewing work dressings having been got from Gellyburn on the Murthly estate. The total cost is estimated at £2,000.

Mr. George Wragge, of Chapel-street, Salford, has recently completed the whole of the wrought iron windows and casements for H.M. Office of Works at the Telegraph Factories, London, and the Parcel Post Offices, Manchester (upwards of 20,000 sup. ft. and 400 casements), and has several further contracts for the Office. Also the whole of the casements at the University College, Liverpool, under Mr. Alfred Waterhouse, R.A.; also upwards of 600 of his special hopper ventilators for the new infirmary, West Derby Union, Liverpool, under Mr. Lancaster, architect, and in addition the window gearing, electric bells, telephones, and the gates, railings, balustrades, and lightning conductors. He is now completing the steel and gun-metal fronts to the cases for the reception of the Althorp Library, recently purchased by Mr. Rylands, to which he is fitting special gun-metal bolts and locks of a new kind, and has recently completed the casement and the whole of the window gearing at the Claybury Asylum under Mr. Hine, architect.

STAINED GLASS.

EDINBURGH.—A stained-glass window, consisting of three lights and tracery, was unveiled at St. James's Episcopal Church, Inverleith-row, last week. The treatment selected is one showing figures of St. George of England vanquishing the dragon, St. Andrew bearing his cross of martyrdom, and St. David of Scotland holding a model of an ecclesiastical building. These are treated in colours beneath an architectural canopy of silvery white. In the tracery openings are introduced banners bearing St. George's and St. Andrew's crosses, and three symbolical plants—the rose, the thistle, and the Italian lily.

KIRKCALDY.—St. Brycesdale Church, Kirkcaldy, has just been enriched with three windows of memorial character. The first and most striking commemorates Patrick Don Swan, for many years Provost of the town. The design is by Mr. Burne-Jones, and it has been executed at the works of Mr. Morris. Incidents in the life of Moses furnish the theme of both compartments. In the first the Hebrew lawgiver is represented in a reclining position as a youthful shepherd, clad in bright terracotta tints, surrounded by the flock of Jethro. In the upper section of the compartment is the burning bush, depicted in the usual highly conventional manner of the artist. Mount Nebo is the scene of the second division, and Moses is being conveyed to heaven by two angels, arrayed in raiment of gorgeous hue, their wings even being of a rich crimson. The other window is a memorial window lately finished of Provost Beveridge, and is on more ordinary lines. The subject is Christ pointing out Nathaniel to the two disciples as the Israelite without guile.

The Sheffield Town Council have adopted a report of a committee recommending the widening of High-street, at an estimated cost of £263,000. Previous street improvements have resulted in wide thoroughfares, the traffic from which is delivered into the High-street, a narrow, winding thoroughfare, producing a congestion which at the busiest times made the street almost impassable. Various schemes have been suggested, with a view of providing a less costly alternative route; but it has now been decided to widen the street on the south side from Fargate to Fitzalan-square, and that the new thoroughfare shall be 80ft. in width.

The Royston Park Estate, Pinner, the first twenty-seven plots of which, for building purposes, are to be sold on the estate on Monday next by Messrs. Debenham, Tewson, Farmer, and Bridgewater, is a good site for the erection of detached residences, which are badly wanted in the neighbourhood. Free conveyances will be given, and the payment, if desired, can be spread over nine years. The land-tax is redeemed, a good 50ft. road is being made on the property, there is good railway communication, and altogether there are few such eligible sites near town.

At a meeting of the joint committee of the Ross and Cromarty County Council held in Dingwall on Monday, it was unanimously resolved to sanction the construction of a new road from Stornoway to Carloway, with a branch road to Breasclete, in the Island of Lewis, and for which a grant of £15,000 is to be paid by the Government, under the Western Highlands and Islands (Scotland) Works Act, 1891, on condition that any expenditure exceeding that sum shall be provided by the Lewis District Committee. The accepted offers for the construction of the road, however, only amount to £14,149 9s. 9d.

Mr. John Chapple, for many years associated with the office of the late Wm. Burges, A.R.A., is the architect of a new nave and aisle in connection with St. Michael's Church, Brighton, and Messrs. Estcourt and Son, of Gloucester, are the builders. The contract is let for £13,000. The foundation stone will be shortly laid, and the first sod was turned the other day with a silver spade, the Bishop of Chichester being present at the ceremony. Mr. G. F. Bodley, A.R.A., built St. Michael's nearly thirty years ago in red brick, with French plate tracery windows, then the fashion with Gothic architects of the more advanced school. The design, as might be expected, had a freshness of its own and an artistic character, which has withstood the changes of taste for its dignity of proportion and design.

The Junior Constitutional Club, Piccadilly, has been fitted to the instructions of Col. R. W. Edis with nine elevators, one a large passenger elevator for the convenience of the members; one a goods and freight elevator, these two being of the regular Otis pattern, with Otis safeties; and six hydraulic service elevators, for kitchen and service purposes. These are of the regular Otis type, but have no safety appliances, the car being so arranged with shelves that attendants or passengers cannot ride. The ninth elevator is a drop lift descending from the ground to the basement floor, which, being a very short rise, has been constructed upon the ram principle.

Building Intelligence.

ABERDEEN.—The new wing of the Royal Infirmary was opened by the Princess Louise last week. The surgical block consists of four stories, three of the upper stories being for wards and the necessary offices in connection with them. The total number of beds for surgical cases is 140. The nucleus of the block, measuring 55ft. by 38ft., contains staircase, hydraulic lift, patients' clothes store, bath-rooms, ward kitchens, surgeons' and sisters' rooms, &c. Right and left of this centre block are the surgical wards. The female wards each measure 22ft. by 27ft. 6in. The floor space allotted to each patient is 90sq. ft., the air space 1,400cu. ft. Each ward has accommodation for 13 patients on the female side and 19 on the male side. In one male ward there is accommodation for 25 beds. Small wards with 6 beds are provided for special cases. Each ward has small projecting wings for sink, lavatories, and sanitary adjuncts. All the ward floors are fireproof, of coke-breeze concrete upon rolled iron joists; the floors are of Canadian maple in narrow width, and are of wax-polished and impervious surface; the walls are of cement plaster finished with Parian; all the passages, corridor, roofs, and staircases have a dado of Parian cement; all angles are rounded; the staircases are of stone, the ward windows are all alternately draw-sash and French casements; rounded balconies face the airing-yard to allow of patients getting an airing. The hospital is heated with hot-water pipes, and will be lighted throughout with the electric light. Mr. Saxon Snell, of London, was the architect.

ASTON, BIRMINGHAM.—New public baths, erected at a cost of £13,000, were opened last week. The style adopted is French Renaissance, and has been carried out in red terracotta with tile roofs. The ladies' entrance is in the centre. To the right are the first-class men's, and to the left the second-class men's, entrances. The building has been planned to economise the labour in working the baths. The first-class swimming-bath is 90ft. by 58ft., being 6ft. deep at one end and 3ft. 6in. at the other, having a water surface 78ft. by 39ft. On either side are arranged the dressing boxes, 44 in number, with brick divisions. The galleries accommodate 400 spectators. The second-class swimming-bath is 72ft. long by 47ft. wide, with a water surface 60ft. by 33ft., of the same depth as the first-class bath. On the sides are 56 dressing boxes. The whole of the baths, except the committee-room, are heated by steam. All the corridors to slipper baths are paved with Minton tiles. The corridors and private baths are lighted with the Swan-Edison type of incandescent lamps. A novelty has been introduced in the first-class baths, consisting of two powerful side lights with reflectors, fixed 3ft. below the water line. The baths have been erected from the designs and under the superintendence of Mr. W. A. Davies, the engineer and surveyor of the local board, Mr. Smith acting as clerk of works. Mr. Stephens, of Aston, is the builder, and Mr. Edwards, of Ruabon, supplied the terracotta.

GULVAL.—Messrs. J. and E. Goad, of the Phoenix Marble Works, Plymouth, have now in hand work for a floor, designed by Mr. J. Piers St. Aubyn, for the chancel of Gulval Church, Penzance, which has been recently restored. The floor is composed of tiles made in the geometrical shapes used in tessellated pavements, the marble being the variegated green obtained at Kitley. It is blended with the rose-colour tinted marble from Radford, and white Sicilian. Some 1,300 pieces, in squares and half-squares, are being used to cover a superficial area of 36 yards. Other floors treated in a similar manner by Messrs. Goad have been sent to Kiungani Chapel and Christ Church (Zanzibar), New Raadzal, Bloemfontein, and the parish churches of Penkridge, Salcombe, and Meavy. The same firm have just completed 150 marble columns, and also marble steps for Budleigh Salterton Church, and a font for St. John's Church, Kensington, the bowl of which weighs 30cwt.

EDINBURGH CASTLE.—The Princess Louise opened, on Tuesday, the Parliament Hall at the Castle, which has been restored by the munificence of the late Mr. William Nelson, from plans by Mr. Hippolyte J. Blanc, A.R.S.A. The building, which is 80ft. by 33ft. has for many years been used as a military hospital. Its fine

open-timber roof has now been renewed, and with its oak-lined walls, stained-glass window with heraldic emblems, carved screen, and old baronial fireplace, the hall will add a new feature of interest to visitors to the Castle. The upper spaces of the walls have been utilised for the purpose of displaying upon them ancient armour and weapons of warfare, obtained from the old armoury at the Castle, and also from the Tower of London. For this mural decoration with armour the design of Mr. John A. T. Bonnar, artist, was accepted. In giving effect to Mr. Bonnar's design, over 2,500 pieces of armour and weapons of various kinds and periods have been used. They consist, for the most part, of examples of coats of mail and helmets of the Cromwellian and other periods, war drums and trumpets, spears, battle-axes, basket-hilted swords and sabres, pistols, and targes, and shields; and along the roof, depending from the open rafters, have been hung a number of old flags, chiefly militia colours of the Early Georgian period. Similar flags furled have been displayed at the sides of the various windows of the hall. Unfortunately, the weapons are not arranged in historical order or sequence, but have been treated merely from a decorative point of view.

EDINBURGH.—The Royal Sick Children's Hospital is about to be rebuilt on a fresh site in Rillbank-terrace (the older structure in Lauriston-lane having been acquired for adding to the Royal Infirmary), from plans by Mr. G. Washington Browne, A.R.S.A., at an estimated cost of between £25,000 and £30,000. The approved design shows a building based, in its style, upon the English Renaissance, occupying three sides of a quadrangle, having the administrative department in the centre block and the wards in the wings. The central building is carried up two stories above the wings, and is finished on its east and west ends with gables with chimneys. A feature of the façade is the large square projecting oriel windows, which balance each other on each side of the central doorway, and are carried above the wall-head to terminate in a gable. Between these projecting oriels, and on the same plane, is the entrance porch. The wards are 140ft. apart, and stand north and south. Each of the four wards is 34ft. 6in. by 23ft., and 15ft. high, and gives accommodation for 24 beds. On the second floor there is in the east block a spare ward with accommodation for 16 patients; while in the west block, on the second floor, is an observation ward with four beds, and two isolated wards with one bed in each. This gives a total of 118 beds in the new hospital. The walls will be of red sandstone, and the floors throughout will be carried on steel beams and lined with cement concrete.

HARROGATE.—According to the local newspapers the building trade was never so prosperous in Harrogate as at the present time. The completion of the Station Bridge improvement is rapidly drawing near. On Monday the continuation of the construction of the new watercourse in Low Harrogate was commenced. One of the most important developments Harrogate has known is Councillor Simpson's handling of the Duchy land from Ripon-road to Cornwall-road. The plans for the development of the Dragon estate have been passed, and operations will speedily begin here, where it is intended to open out twelve new streets. On the Spring Bank estate several semi-detached villas are being erected. The new wings at the Hydropathic establishment are rapidly approaching completion, while the buildings at Harlow Manor have been largely augmented for a new Hydropathic Company. The West End Park estate is being rapidly developed, and a large number of building sites have recently changed hands and building operations commenced. In the immediate vicinity buildings are being erected, and the town was never apparently in such a prosperous condition.

HENSHAW.—The memorial stone of a new chancel and vestries about to be added to the parish church of Henshaw, near Yeadon, was recently laid. The buildings will supersede a chancel and vestries of very diminutive proportions. The chancel will be 29ft. by 19ft., and opens into the nave by an elevated and moulded arch, supported by clustered columns. It will be lined throughout with bolstered ashlar, and will contain at the east end a five-light window with Geometrical tracery in the head. It is divided into three bays, each of which contains a clerestory window filled with tracery. To the north of the chancel, and opening into it by an

arch of a similar character, will be placed the organ-chamber, and to the south will be the choir and clergy vestries. In the chancel sedilia and credence tables will be worked into the main wall of the building. The nave will be re-seated with polished walnut seats, and an organ and a memorial stone pulpit will be erected as special gifts, and new floors will be laid throughout. The architects are Messrs. T. H. and F. Healey, of Bradford, and Mr. James Taylor, of Yeadon, is the contractor. The work is estimated to cost £1,800.

JERSEY.—The new church of St. Aubyn is approaching completion. It is built entirely of granite, the exterior walling being of pink Mont Mado granite with dressings of grey Perruque granite; the quoins from the former chapel were utilised where possible. The interior is plastered, with pink Mont Mado columns, arches, and dressings. The dimensions are 94ft. by 41ft. The roofs are trussed open-timber, of fir, boarded inside and covered with Broseley tiles. The flooring under the seats is of wooden blocks on concrete, while the passages and chancel are of coloured tiles in patterns. The church consists of nave, aisles of five bays, chancel, chancel aisle, organ chamber, and vestry. A tower and spire will ultimately be built at the south-western angle. The church will seat 340 people, the seats throughout being of oak. There is a reredos of alabaster with bronze shields bearing emblems of the Evangelists and the sacred monograms, executed by Mr. H. T. Margetson, of Chelsea. Three stained-glass windows are the work of Messrs. Heaton, Butler, and Bayne, of London. The style is Early English. The church and fittings were designed by, and carried out under the superintendence of, Messrs. J. E. K. and J. P. Cutts, of London. The contractors were Messrs. Woodsford and Harris and Mr. T. Blampied, and Mr. J. Laurens was the clerk of the works.

LICHFIELD CATHEDRAL.—Towards the £20,000 appealed for for restoring the fabric of the Lichfield Cathedral the committee have so far received donations or promises amounting to upwards of £5,000. With this sum in hand the Dean and Chapter have undertaken the following portions of the work: (1) The restoration of the large window in the north transept; (2) the insertion of new mullions and tracery in two of the windows of the Lady-chapel; (3) the repair of the western side of the north transept, which was in a dangerous condition; (4) the restoration of the southern and eastern faces of the central tower. The Dean and Chapter, with the entire concurrence of their own architect (Mr. John O. Scott), have sought the advice of Mr. John L. Pearson before proceeding further. Mr. Pearson has inspected the cathedral, and has presented his report, in which he states that the condition of the south transept is by no means satisfactory. Considerable restoration is needed on each side of it; but more especially on the west side. He should be disposed to leave the design of the great south window as it now is, and no alteration should be made in the curious tracery in the circular window in the gable. It is absolutely necessary to restore to some extent the decayed stonework of the windows and buttresses of the north arch of the nave. Much external reparation is needed to walls, windows, &c., of the chapter-house and vestibule. The damage done by the falling of the spire to the vestibule should be made good, and he would include the restoration of its groining. The chapter-house is a building of so much interest that no pains should be spared in rearing its lost and decaying features.

SALT.—The reopening of St. James's Church, Salt, near Stafford, after restoration, took place on Thursday last week. The church was built by Charles, second Earl Talbot, in 1842-3, and is constructed of Weston stone, in the Early English style, comprising nave and chancel, south porch, and eastern bell-cote with spirelet. The alterations just completed consist of the removal of the west gallery and the whole of the old pewing in the nave, in place of which solid benches of pitch-pine have been substituted. The stone-flagged flooring has been taken up, and wood-block flooring (A. F. Whittome's patent) laid under the part occupied by the seats and the passages with tiles. The under surface of roof has been covered with pitch-pine boarding. The bowl of an ancient font, which had been for some time in the churchyard, has been restored and adapted to a new shaft and base. The old stone pulpit has been

replaced by one of oak, from the designs of a well-known Exeter firm. The alterations have been carried out by Messrs. Adams and Pemberton, from the designs of Mr. N. Joyce, architect, Stafford, at a cost of £500.

WEST DERBY, LIVERPOOL.—A hospital is being built for the West Derby guardians. It is constructed of grey and red brick with terracotta and sandstone dressings. The administrative block is enriched with terracotta, and has a projecting porch of red sandstone. It is designed in the Elizabethan style. The ground plan of the hospital is a double H, thus; |—|—|, and consists of five ward blocks, the central anterior limb being the administrative block. The administrative block consists of four stories, including the basement. The basement contains porter's room and dormitory, bath-room and lavatory, mess-room, and store-rooms. On the ground-floor are offices and sitting-rooms for the staff, dispensary, committee-room, kitchen, pantries, and lavatory. On the first floor there are bedrooms and bath-rooms for the medical staff and matron, and linen and sewing rooms. On the second floor there is bedroom and bath-room accommodation for the house servants of the staff. Between the administrative block and the ward block behind is a kitchen, the walls of which are built of white glazed brick with dado. It is lighted from the roof, and connected by hydraulic lifts with each ward. On each side are the male and female receiving-rooms, with bath-rooms attached. There are 20 wards, 16 of which are 108ft. by 24ft. and 14ft. in height, containing 36 beds each. The remaining four wards measure 96ft. by 24ft. and 14ft. high, containing 32 beds each. At the rear is the older lunacy annexe, containing 150 beds, making a total of 1,000 beds. The ward floors are of pine blocks laid in asphalt on concrete. At one end of each ward there are a day-room, a separation ward for two beds, a duty-room, and two linen-closets. At the other end of each ward and forming an annexe are bath-room, water-closets, and sink. Separated from the hospital by a road, but connected by a subway, is a nurses' home, three stories in height. The architect of the buildings is Mr. Charles Lancaster, and the contractor Mr. E. Gabbutt, both of Liverpool.

YORK.—The Lord Mayor of York opened on Wednesday the new law courts, police, and fire-brigade stations. The buildings are situate at the corner of Clifford-street and Lower Friargate, near the Castle. They have been designed by Mr. Huon F. Matear, F.R.I.B.A., and the work has been executed under his personal superintendence. The style adopted is a free treatment of Gothic. The external elevations was faced with red pressed bricks, with Staindrop stone dressings to the doors and windows. The main entrance in Clifford-street is surmounted by a gable filled in with subject carving representing King John creating the first Lord Mayor of York, and terminated with a figure of "Justice," behind which rises a clock tower constructed in oak, with clock and bell by Messrs. Potts and Sons. A bust of the late Duke of Clarence, executed by Mr. Williamson, of Esher, has been placed in the entrance-hall. The principal apartments on the ground floor are the session and police courts, placed end-on to each other, and there are also rooms for judges, magistrates, and magistrates' clerks, and the petty juries. On the first floor are the grand jury room, and a suite of rooms for the school board, and the second floor provides apartments for the caretaker. The police station and offices are situated in Lower Friargate, and under the courts, and entered from the corridor are twelve cells for prisoners awaiting trial. Constables' apartments are provided on the floor above police office, while a drill-yard is entered from Lower Friargate. The police-station is placed at the lowest corner of Lower Friargate, and along the river front of the building there are quarters for firemen and their families, and a resident superintendent. The furnishing and decorations have been executed by Messrs. Waring and Sons and Messrs. Belleby and Sons. The principal contractors for the works were Messrs. Parker and Sharp, of York, and Mr. English acted as clerk of works.

The Infectious Hospital, Widnes, is being warmed and ventilated by means of Shorland's patent Manchester grates and patent Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

Correspondence.

ARCHITECTURE: A PROFESSION OR AN ART?

To the Editor of the BUILDING NEWS.

SIR,—At last the threatened thunderbolt has fallen in the shape of "Thirteen Short Essays on the Qualifications and Training of Architects," edited by R. Norman Shaw, R.A., and T. G. Jackson, A.R.A., and published by John Murray, Albemarle-street.

It is somewhat difficult to understand why one or two of the essayists were imported into the undertaking, except on the ground that numbers have an appearance of strength, and that whether or not the writers had sufficient technical knowledge of the subjects upon which they have elected to inform the public, still there is the essay; and one or two sentences may, after all, "catch on," and so a weak cause receive a little buttressing, every inch of which is needed.

We can dispose of the numberless platitudes and truisms which occupy, at least, 75 per cent. of the thirteen essays by the remark that, however interesting they may be in the lecture theatre of a students' college, they can have very little weight in a controversy of this kind, and they have not even the merit of being clothed in that respectable English which sometimes gives an appearance of reality to an intangible dream.

Mr. W. B. Richmond, A.R.A., gives us his "Thoughts on Three Arts and the Training for them," and I shall be better able to judge of the true value of his "thoughts" when they are elevated to *practice* in the work he is commissioned to do in St. Paul's Cathedral.

Mr. John R. Clayton, in "The Isolation of 'Professional' Architecture from the other Arts," has been injected with the utterly erroneous view that the Institute does not, in the very highest degree, pay tribute to "art," in its noblest form, *when it is to be seen*;—the great difficulty always is to lay one's finger upon the precise spot where modern "art" in England stands out as undeniably as it does in the old works in Belgium, France, and Italy. Of course, we are duly grateful to Mr. Clayton for informing us that "it is of supreme importance that edifices which stamp the aspect of our cities and public places, to our credit or discredit as an artistic people, should bear marked evidence of our regard for architecture, not as a profession, but as an art," and one is tempted to point out to him that so long as our edifices bear "marked evidence of our regard for architecture," it matters little whether the result is due to "profession" or "art."

Mr. J. T. Micklethwaite heads his essay "Architecture and Construction." He has his fing at the Institute, and finishes up with the satisfactory remark that "already the proportion of buildings which rise to the level of architecture is greater than it was." It is a thousand pities that he did not tell us what he meant by "was," and name a few of the structures which exhibit the rise in level to which he refers.

Mr. Gerald C. Horsley meanders along under the title of "The Unity of Art" till his emotion gets the better of him, and, speaking of Sedding's Holy Trinity Church at Chelsea, he tells us that certain spaces in the roof and the broad frieze were "lovingly" prepared by Sedding for paintings by Burne-Jones. I do not know that "cant" can go further than this, and I desire to express my deep condolence with Mr. Norman Shaw, as one of the editors, in not eliminating from Mr. Horsley's essay the ungrateful smack the latter gentleman has at his chief in the following sentence: "Instead of seeking reconciliation with the sister arts, architecture has taken refuge in a series of revivals of mere forms of past art, thus producing links which of necessity have less vitality the nearer they succeed in approaching their models." The italics, Sir, are mine.

Mr. Mervyn Macartney, in "The Protection of the Public," is harmless, except when he misstates the assurances given by the Institute as regards its members, and Mr. Ernest Newton, in "Architects and Surveyors," has a good go at the "practical architect"—dreadful man that "practical architect"—having previously smartened himself up by the sublime "thought" that "there will be no real life and natural development in architecture till the architect is brought more into contact with his work, seeing it develop day by day, 'meeting and overcoming dif-

ficulties as they arise," &c. Yes, Mr. Newton, there are several architects in London who would like to be brought more into contact with their works if you would only show them where the works are.

Mr. Edward S. Prior writes under the head of "The Profession and its Ghosts," and Mr. W. R. Lethaby in "The Builders' Art and the Craftsman" takes up twenty pages of the book in proving the utter impossibility of his contention; and Mr. Reginald Blomfield, in "The Institute Examination and Architecture," labours hard to throw discredit upon the Institute and all that it does.

The other essayists are Mr. Norman Shaw, R.A., who writes under the title "That an Artist is not Necessarily Unpractical," Mr. G. F. Bodley, A.R.A., under "Architectural Study and the Examination Test," Mr. Basil Champneys, B.A., on "The Relation of General to Technical Education in the Training of an Architect," and Mr. T. G. Jackson, A.R.A., on "True and False Ideals in the Education of an Architect."

Now the whole object of the latter four gentlemen appears to be to endeavour to prove to the public (1) that the Institute system of examination is bad, that it ignores the claims of true art, that no man who follows its precepts can ever rise to the pinnacle of real architectural merit to which these gentlemen have attained, and that (2) they, not being members of the Institute, have, somehow or other, been endowed with superior art faculties, which have enabled them to bestow upon the world the most glorious examples of artistic excellence, the dreams of gods, the ideals of poets. In the desire to impress their extraordinary powers upon a confiding British public they quietly ignore the challenge I threw out to them to state how much of many architects' work is relegated to the "specialists" whom I set forth in the *Times* during the controversy in November, 1891. Now I ask Mr. Jackson and Mr. Norman Shaw to believe me when I say that, if I could find works of theirs which to my mind exhibited the art feeling so much insisted upon by them in their writings, I should be one of the first to express my admiration in unqualified tones; but facts stare me in the face which I am powerless to pass over. For example, some of Mr. Norman Shaw's well-earned reputation was gained by his beautiful little "Lowther Lodge" at Kensington; but a few years after he did not hesitate to crush its proportions and to utterly mar its artistic effect by erecting that monstrous and ugly flank wall of the Albert Hall Mansions next door to it. I want to know where the art feeling comes in there?

Mr. Basil Champneys has just erected an hotel in Kensington High-street, which, for stupendous and unmitigated ugliness, is not to be beaten by any modern building in London. I should like to be informed by Mr. Champneys where to look in that building for the result of his wonderful art knowledge, and I ask him to accept my assurance that if he will deign to point out the beauties of his hotel, I will immediately withdraw every word I have said against it, and apologise to him for my ignorance.

Mr. Bodley has occupied for about two years the choir of St. Paul's Cathedral in "decorating" the stonework. The "cream and gold," which formed the leading basis of the scheme is now to be got rid of, and the cathedral is to be restored to its original appearance, so that, after two years of opportunity, the authorities have to go back to "as they were" (if they can, which I much doubt), because somehow or other the "art" did not come up to expectations. Where is the superiority here?

Mr. T. G. Jackson has, in the quadrangle of Hertford College, Oxford, made some additions which are positively startling. A new external staircase here, as regards lines, proportions, and details, is one of the most extraordinary efforts to be found even in modern work in Oxford. It is utterly devoid of art feeling, and is, to my mind, a very regrettable piece of work. Where is the art here?

As I have said time after time before, I am not content to be told by any number of Mr. Jacksons or Mr. Shaws that they are the real "Art" men, and that Institute men are a mere set of surveyors, agents, &c., without any feeling or capabilities. I ask to be told where the Art works are to be found, and silence is the reply. Let Mr. Jackson tell me where to look, and I will at once look; but tons of words—words—

words—have not, with me, one-tenth the effect of works—works—works. Measures, not men; sincere feeling, not cant.—I am, &c.,

WM. WOODWARD.

13, Southampton-street, Strand.

ARTISTIC "FELLOWS" AND ORDINARY "MEMBERS."

Sir,—Among the welcome things one reads this year in the professional Press on one's return from the summer holiday are two letters appearing in one of your contemporaries, signed respectively by Mr. John Belcher and Mr. John Brydon, supporting a proposal which, if carried out, would, I believe, go far to advance the cause of pure architecture.

The proposal, briefly stated, appears to be that, while a compulsory examination should be still applied as a test of ordinary membership of the Institution, the Fellowship should be given in recognition of artistic merit only, which, as the authors of these letters truly remark, is a necessary qualification to the title of "architect."

It would be suicidal on the part of the R.I.B.A. to abandon the examinations (never mind by what title they are known), for the simple reason that the public do not, generally speaking, demand a high standard of artistic work; but they do demand thorough acquaintance with the planning, constructional, sanitary, and business side of architecture, knowing, naturally enough, that consideration of convenience and health come even before art.

Unfortunately, the present limited application of this examination does not allow of our telling the public that, in engaging an architect, they may have confidence in his qualifications to this very important extent. When a Registration Bill is passed we can do so, and if Mr. Belcher's proposal is adopted, those of the public who want an artist as well as a man of business can some day depend on getting one by selecting a Fellow of the R.I.B.A.

Although the public do not demand a high art standard, they do expect some taste and power of delineating one's ideas, and the possession of both these qualifications, though not their degree, can be sufficiently tested for this purpose. We must take care, therefore, that these subjects continue to form part of the examination for Associateship.—I am, &c.,

W. H. SETH-SMITH.

WALSALL PUBLIC BATHS COM-PETITION.

Sir,—From the reports of the Walsall town council meeting when the above competition was settled, I gather the following facts: Two of the three premiated designs will not go on the land, the first encroaching on the land reserved by the council for the erection of shops; the design placed third takes in 3ft. of the land on the left-hand side of the site; neither the first nor second designs has separate entrances to the female slipper baths; there is only one entrance to design No. 1, over which coals and everything have to be taken; no provision for replacing the boilers is made. I have heard it said that if this plan is carried out, and anything goes wrong with the boilers, the baths will have to be pulled down to take in a new boiler. The third design has no waiting-rooms. The committee were advised in their selection by the borough surveyor, who is spoken of by the mayor as an eminent architect.

Probably many competitors will think, with me, that none of the premiated designs ought to have been selected.—I am, &c.,

DISGUSTED COMPETITOR.

LAND SURVEYING.

Sir,—Will Mr. Cobham turn back to my letter of October 7th, and favour me with a straightforward, point by point, reply?

We need no differential calculus (of which, by the way, I know quite enough to enable me to detect Mr. Cobham's false premises—but that is neither here nor there), or any kindred operation, applied to so simple a question. That is like using a hundred-ton gun to play at marbles with. What I look for, and what I think I (and your interested readers, if any such there be, are as well) am entitled to, is a direct reply, Aye or No, to the following points raised by the letter before alluded to: Are my figures given there substantially correct, or are they not? If they are not, give the correct ones. Is 5.5 (approximately

even) the half of 24? Or 4 (approximately even) the third of 24? Is a loss of three-fourths of efficiency (my check is 25, his is 7) a trivial matter?

As to Fig. 4, will Mr. Cobham explain what difference it makes in plotting whether the line B C is measured from B to C, or *vice versa* providing the error of 40 links is kept between B and D in each case. If he desires to have us believe that he has placed the error between D and C (and in no other way can A F be altered anything like 23 links) then he will excuse me saying that he has been setting up a ninepin of his own to knock down again, and will pardon my asking him to turn his attention to mine, which is, so far, intact. I have carefully located the error between D and B from the beginning, and Mr. Cobham has so far given no indication of any misunderstanding on his part whatsoever, so I may have misjudged him. If so, I beg his pardon. Whether or no, will he embody in his reply an opinion whether I am correct or not in my letter of October 7th when I say that A F is no check on the length of B D, and if it is not (he seems by his last letter to have abandoned it and flown to E D as the check, although, *more suo*, he doesn't deliberately say so), will he say whether my statement, that D falls about three links inside or outside C B, according as D B is lengthened or shortened 40 links, is correct? And if, in his opinion, a variation of three links is a sufficient, a reliable, and a trustworthy check?

Never mind about the competent authorities; let us do a bit of thinking for ourselves, and, taking Mr. Cobham's advice, let us "not allow a hard and fast rule to override the needs of particular cases, every one of which demands a little extra study."

He might, perhaps, in his reply tell us why, on August 5th, five links was such a short length and so hard to plot, and on September 23rd seven links was such a long length and so easy to detect.—I am, &c.,

NORTHMAN.

BRICKS.

Sir,—Referring to the remarks in your last issue respecting the Hetton bricks, my experience of them agrees with the report thereon, except that for damp situations and where exposed to weather they will not, I think, bear comparison with a good hard London stock. I believe in their manufacture they undergo machine pressure, consequently all moisture is taken out, and so soon as the face of the bricks is destroyed they crumble away. I have seen this occur very largely in dwarf walls where they have been used. For inside work, they are a first-class brick; but I should hesitate to use them in damp or exposed situations. I shall be glad to hear other opinions.—I am, &c.,

WM. THEOBALDS, Architect.

26, Budge-row, London, E.C., Oct. 18.

CHIPS.

Mr. J. Passmore Edwards, says the *Daily News*, who has recently built and endowed the Cornwall Convalescent Home at Perran Porth in memory to his mother, is building an educational institute to the memory of his father at Hayle; and a library and scientific institute at St. Agnes to the memory of his elder brother, and a school and meeting-room at St. Day in memory of his late uncle, John Edwards. All the places mentioned are in Cornwall.

A new branch bank for Lloyds, Limited, has just been completed at Bexhill-on-Sea. It is faced with local red bricks, with moulded Beaufort brick designs. Mr. Arthur Wells, of Hastings, is the architect, and Mr. Peter Jenkins, of St. Leonard's-on-Sea, the builder.

The Home Secretary has appointed Mr. Robert Collier Driver to succeed the late Mr. Ryde as one of the arbitrators in connection with the Boundary-street scheme of the London County Council.

The London County Council has decided to deal with the Peckham-rye Extension as a place to be closed at night time, but not as a park. Mr. Blashill, their architect, has been requested to bring up an estimate to provide for the erection of a suitable open iron boundary fence. The decision of the Council is in accordance with resolutions passed by the committee which negotiated the scheme, and also by the Camberwell Vestry.

The Dean and Chapter of Peterborough decided yesterday to accept the offer of "A Friend" to provide a new organ for the cathedral at a cost of £3,000. A condition of the gift is that the donor's name is not to be divulged.

Intercommunication.

QUESTIONS.

[10870.]—**Dry Rot.**—Will someone be good enough to favour the querist with his experience with regard to curing an advanced case of dry rot? The building affected stands high on chalk, and is situated as shown by rough sketch. The timber in cellars and the floors of kitchen and offices are the parts attacked. The cellars are damp, and when first brought under my notice unventilated. I fixed ventilators in opposite walls to create a draught, and removed rotten woodwork, fixed new timber, and thoroughly dressed it with turps and red

lead. The fungi shortly after appeared on the new work, and in spite of frequent scraping and dressing with red lead is spreading. What is the best remedy, and can any dressing be applied to the walls and woodwork capable of exterminating the nuisance? An early practical reply will much oblige.—EX-WISE-ED.

[10871.]—**Overhanging Cornices.**—Is an overhanging eaves cornice permissible? Can the adjacent owner make any legal objection if the gutting is properly fixed, and what is the law of the case?—E. T.

[10872.]—**Covering Area of Building with Concrete.**—Is this by-law in operation everywhere within the Metropolitan area? If so, how is it many new houses are erected without it? Perhaps some practical official of the L.C.C. can inform.—PERPLEXED.

[10873.]—**Boasting.**—What is the meaning of "boasted" work in masonry? If any reader of your journal could inform, it would probably instruct others besides.—ONE WHO WISHES TO LEARN.

[10874.]—**Roofing of Space.**—I have a roof to design which will be wider at one end of the building than the other. Can any practical man tell me how to get over the difficulty without injury to the external effect? Any ideas will be gladly received.—YOUNG ARCHITECT.

[10875.]—**Drainage of Dwelling-Houses.**—The model By-laws of the Local Government Board, after requiring a disconnection of drains within the curtilage of a house from the main sewer by means of a trap, proceed to direct, taking one of the alternatives, that an untrapped opening to the drains shall be provided at the level of the ground on the house side of the trap to act as an air-inlet, and that at the highest point of the system a vertical pipe be fixed, to act as an upcast shaft or extractor. It also permits the soil-pipe to connect directly with the drains, and perform the duty of an extractor for the gases or foul air. Can this be considered a desirable or safe arrangement? The committee of a public authority with which I am connected are now engaged in revising and adapting these by-laws, and I advise the entire disconnection of the soil-pipe with the drains, and suggest a separate pipe for ventilation. It appears to me that, considering the risk of unsealing the closet trap by siphonage, evaporation through constant use, leakage through cracked earthenware or other cause, is constant and great, and in such event the house becomes at once the exhaust for the drains. I shall be glad to have opinions on this point, which, to my mind, is of first importance.—P.

REPLIES.

[10833.]—**Timber and Its Position.**—Why does not S. F. Harris say in what wood he has seen the sap-valves which he described as opening upwards; or, in the alternative, state the source of his information, instead of advising me to "read some authorities on timber and its growth"? I did that half a century ago, and have since examined numerous specimens of plant structure, both in the form of recent growth, and also of seasoned timber. The circulation of the fluid contents of plant cells, as seen under high powers of the microscope, is also familiar to me, but the sap-valves which your correspondent mentions have hitherto escaped me. I do not say they are non-existent, for I believe we have not yet got to the bottom of the mystery of sap circulation, and I am well aware of the difficulties to be overcome in the demonstration of many of the most minute parts of plants. If, however, your correspondent will enable me to find the valves, I will endeavour to illustrate them by a drawing, and will send it to you, Sir, for the benefit of your readers, should you see fit to use it.—E. S.

[10837.]—**Testing Drains.**—With reference to Mr. Buchan's suggestions on this subject on p. 543, and his criticisms on mine of last week, I should like to say that on several occasions I have found the spike-test inefficient in determining defects which the ether test has once located. I do not, however, suggest that I have used a similar machine in applying the test as he mentions. Then as to the ether test being "too indefinite for a court of law" in his opinion, I can only say, with reference to that statement, that I have proved a case of defective drainage in a law court by the ether test, which was accepted by the learned judge as absolutely sufficient proof of the defects. There is no doubt, however, that unless this test is very carefully applied by well-qualified operators there is the risk of unfair condemnation, as suggested by Mr. Buchan, which should be particularly guarded against, in the interests of all concerned.—C. EST.

The enlargement of Brompton Hospital chapel having been completed, the Bishop of London will reconsecrate it to-morrow (Saturday).

Legal.

THE NEW STREET WORKS ACT.

THE Private Street Works Act, 1892, briefly noted last week, contains several clauses which are of immediate interest to architects, surveyors, and builders. The statute gives so many advantages over the Public Health Act, 1875, that it is pretty certain to be rather generally adopted by urban sanitary authorities, while it is also likely to be applied by order of the Local Government Board to rural districts. Sections 9 and 10 are especially of practical importance. By Section 9 the local authority may include in the works to be done under this Act, with respect to any street, any works which they think necessary for bringing that street, as regards sewerage, drainage, level, or other matters, into conformity with any other streets, including the provision of separate sewers for the reception of sewage and surface water respectively. Here we have a power to make needful and permanent improvements far beyond the ordinary paving, making, &c., of a new street, but which must, when used, increase the expenses. This method of raising levels, and getting better drainage, is a step in the right direction, though it may, and indeed must, impose heavier burdens upon new properties. The other part of this clause settles a vexed and undecided question, by enabling the local authority to add a commission of 5 per cent. beyond the estimated cost of the works in respect of surveys, superintendence, and notices, which is to be carried to the credit of the district fund.

Section 10 is, however, even more of an innovation, for it distinctly recognises the principle of betterment, and applies it practically. This is done by providing that, although in the preliminary and provisional apportionment of the expenses of private street works, the frontages of the respective provisions shall be considered as before, yet the local authority shall have regard to the following considerations:—“(a) The greater or lesser degree of benefit to be derived by any premises from such works; and (b) the amount and value of any work already done by the owners or occupiers of any such premises.” Further than this, it is declared that they may also include any premises which do not front, adjoin, or abut on the street, but access to which is obtained therefrom through a court, passage, or otherwise, and which in their opinion will be benefited by the works; and may fix the sum or proportion to be charged against these other premises accordingly. In other words, while the local authority can increase the expense of new street work by doing it better and more thoroughly they can also extend the area of the premises, amongst the owners of which that expense is to be apportioned. They can also regulate that apportionment by having regard to the benefit gained from the works to be done by each house or premises, according to its situation, and this, of course, is only to apply the principle of betterment in a fair and reasonable manner.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed “BUILDING NEWS,” and must reach my offices, as above, by Tuesday morning to insure answer same week.

R. AND S.—REBUILDING.—ADJOINING OWNER.—If the work is carried out in a proper manner, and without any unusual noise, it would not legally amount to a nuisance, and I do not see what proceedings can successfully be taken by the adjoining occupier as he threatens; though he may, of course, bring an action for damages if he likes.

CONSTANT SUBSCRIBER.—SURVEYOR.—You could make valuations of the kind suggested, if for the information of one party only, and not binding on both, without any license as an appraiser. No. 5 in your list would also be lawful. But as to the other four cases, if the valuation is really for both sides, or is to be received in evidence, a license would, strictly speaking, be necessary, and so would a stamp upon the valuation itself.

NORSEMAN.—ARCHITECT.—CHARGES.—The three per cent. remuneration payable to an architect when the work has gone as far as accepting tenders and is then abandoned, has nothing to do with taking out the quantities. This is usually paid to the quantity surveyor, and must be arranged for separately.

T. M.—LEASE.—NOTICE.—As the taking a lease appears to have been given up or waived by both parties, and a yearly tenancy created by B. occupying and paying A. a yearly rent, as I suppose, he can only quit after giving A. the usual six months' notice, to expire at the end of a complete year of such tenancy.

ECCLDS.—SEWER.—DRAIN.—Under the Public Health

Act I consider this would be a “sewer,” as it goes under a road and is not merely a drain for the purpose of draining premises “within the same curtilage.” Regarded as a sewer, the owner should be called upon to provide the proper ventilation, &c.

LEGAL INTELLIGENCE.

A CORPORATION FINED FOR RIVER POLLUTION.—On Thursday in last week, at the police court at Bury, Lancs, the case against the Bury Corporation for the pollution of the Irwell and the Roach, taken at the instance of the joint committee of the Mersey and Irwell Rivers Pollution Board, was resumed. The magistrates ordered the mayor, aldermen, and burgesses to pay a fine of £5 and £20 costs in each of the two cases, and further ordered that the liquid sewage matter be diverted from the rivers Roach and Irwell within twelve months.

INTERCEPTION OF LIGHT AND AIR.—WOODWARD v. MOULDER.—At the Cheltenham County Court on the 11th inst., Judge Elliott gave judgment in this case, the evidence and arguments in which were completed at the August court. He said:—This is an action brought to recover £50 damages for an alleged obstruction to light and air. Up to May, 1891, the property which is the subject of the action consisted of two freehold tenements, Nos. 1 and 2, Clare-cottages, Bath-road, standing some distance back from the line of frontage, with a small garden in front of each. On May 21, 1891, the common owner of both properties sold No. 1 to plaintiff and No. 2 to defendant. The plaintiff continued to occupy No. 1 as his dwelling-house. The defendant afterwards built a shop on the garden in front of his house 24ft. long, 17ft. wide, and 11ft. high, and the plaintiff now brings an action for the damage he has sustained thereby. The substantial ground of action is the loss of light. The expert evidence called on behalf of the plaintiff showed that rather more than half the window was affected by the shadow thrown by the wall, which would appreciably darken even the middle of the room. For the defendant it was urged that the obstruction was lateral and only affected a small portion of a single window, and it was suggested that the room would be light enough if the curtains were removed. The expert evidence for the defence denied anything like a substantial diminution of light. One witness called it very immaterial, another said there was theoretically a slight obstruction but practically none, a third characterised the whole as “rubbish.” After viewing the premises, and after hearing the evidence on both sides, my opinion was that though the obstruction is lateral only, still there is an appreciable diminution of light, and that the house is distinctly less commodious than it was. Mr. Wagborne, for defendant, submitted several points of law. The fact that the properties were formerly held by one owner does not affect the question—there is no difference in principle between the case of a contemporaneous sale by a common owner of a house and land to one person and an adjoining house and land to another person, and the case of a sale of a house to one and of the adjoining land to another. In neither case is the purchaser of the land, whether with or without a house upon it, entitled to build so as to obstruct the ancient lights of the adjacent house. I do not lose sight of the fact that the plaintiff only paid £230 for his house and garden, and I assess the damages at £30.

CONCRETE BEDS AND THE BUILDING ACT.—At Lambeth police court on Tuesday, Charles Watts, builder, Lower Kennington-lane, appeared in answer to five summonses issued by Mr. Ellis Marsland, M.S.A., district surveyor for Camberwell, for having, in the construction of some houses in Worlingham-road, East Dulwich, covered the site with other than a layer of good concrete at least 6in. in thickness. Mr. Biron, the magistrate, who had personally visited the houses, pointed out to the defendant that the material used had been very imperfectly mixed, and did not conform to the requirements of the Building Act, which required that the material should be absolutely impervious to moisture. The defendant said he was ready to carry out the work to the satisfaction of the district surveyor. Mr. Biron said that upon that understanding he would only impose a nominal penalty. He ordered the defendant to pay a fine of 20s. and 2s. costs on the first summons, and a fine of 1s. and 2s. costs on each of the other summonses.

LIABILITY FOR BAD DRAINAGE.—At the Clerkenwell county court on Tuesday, before Judge Eddis and a jury, Lancelot Hoskins, of 91, Corbyn-street, Upper Holloway, sued Mrs. Corfield, of 90, Atlantic-road, Brixton, for £13 10s. damages for misrepresentation as to the sanitary condition of 91, Corbyn-street. From the plaintiff's evidence it appeared that in 1891 plaintiff became tenant of 91, Corbyn-street, the property of the defendant, who assured him it was in a perfectly sanitary condition. A fortnight later he detected bad smells in the house, and a day or two later one of his children suffered from gastric derangement, caused, the doctor said, by sewage gas. Walter Ward, sanitary inspector in the employment of the Islington Vestry, proved the

faulty condition of the drainage. It was pointed out by the Judge that unless the statements made by the defendant to the plaintiff were dishonest—unless she, knowing that the drains were defective, said they were not—the plaintiff's case must fail.—The jury found a verdict for the plaintiff for the amount claimed, and costs.

RE CHRISTOPHER EVERARD.—The debtor, a builder, carrying on business at Stratford, recently filed his petition, and in the summary of his accounts the liability is returned at £3,315, of which £2,885 are unsecured, and the assets at £749. The debtor has been adjudged bankrupt. He attributes his failure entirely to loss in respect of a contract for the erection of the Victoria and Albert Dwellings in South Lambeth-road, his loss whereby he estimates to have amounted in all to about £2,700.

IN RE W. ROBERTS.—A receiving order has been made against William Roberts and Robert Percy Nugent, carrying on business as builders at 95, Little Cadogan-place, Chelsea, under the style of “William Roberts.” The debtors return their liabilities at £6,283, of which £4,773 are unsecured, with estimated assets £1,736, and a deficiency of £3,093 is anticipated. The debtors commenced business in April, 1889, with £500 capital, contributed by the debtor Nugent, to whom that amount was lent by his father. Mr. Nugent, sen., is treated in the statement of affairs as a creditor for £2,265, exclusive of the £500. They assert that, apart from their ordinary business, they have incurred heavy losses in connection with speculations in the purchase of resale and leasehold property. The assistant official receiver states that the books do not sufficiently disclose their business transactions or their financial position at any time.

COMMISSION FOR SALE BY PRIVATE CONTRACT.—LIELL v. BOULTER.—In this case, heard at Bow County Court on the 14th inst., plaintiff is an auctioneer and defendant a builder, of Romford-road, Stratford. The claim was £49 on account of commission. In September last plaintiff was employed by defendant to sell by auction seven houses in Skelton-road, Forest Gate. The commission was to be 2 per cent. The sale was attempted, but the property not disposed of. Subsequently, in February the houses were sold by private contract to Mr. Samuel Jones, of Stratford, for £2,450. On this amount plaintiff now claimed 2 per cent. The questions before the jury were three in number. First, was plaintiff engaged to dispose of the property by private contract? Secondly, had the purchase by Mr. Jones been brought about through the instrumentality of plaintiff? Thirdly, what was the amount plaintiff was entitled to claim, if any? The jury found a verdict for the plaintiff for £30. His Honour gave judgment for the amount, with costs.

CHIPS.

The Dore and Chinley Railway, to connect Sheffield with Manchester by an easy route on the Midland, will be opened in June next. A great engineering feat has been accomplished in the construction of the Totley Tunnel, which is 3½ miles long, without a single air shaft. The new line will cost £1,000,000.

Sewerage works are about to be carried out at Totland Bay for the Isle of Wight rural sanitary works. Mr. Lidstone is the engineer, and the contract has been taken by Messrs. Trowsdale and Co. at £4,050.

On Thursday in last week a new church, just completed for the Wesleyan body at St. Anne's-on-the-Sea at a cost of £4,200, was opened for worship. The style is Decorated Gothic, and the building has a lofty spire, which will be a landmark for the whole district. The church, which is built of Yorkshire pitch-faced stone, with roofs of Westmorland green slate and red ridge tiles, consists of nave and chancel, with very slightly developed transepts, and an east gallery, the seating accommodation being for 490 persons. There is also an organ chamber, a choir vestry, and a minister's vestry.

A stained-glass window, erected as a memorial of the late Right Hon. Henry Cecil Raikes, Postmaster-General, has been placed in the side of the south transept of Chester Cathedral. The window, which has been subscribed for by residents in Chester and the county, bears the four figures of St. Chad, St. Martin, St. Anselm, and St. Asaph, with scenes connected with the lives of these saints.

The ancient church of Carlton-in-Lindrick, Work-sop, which seems to have consisted originally of tower, nave, and chancel, with aisles, has been restored at a cost of £900. Mr. Charles Green, of Rotherham, was the contractor. The reopening services took place on Saturday, with the Suffragan Bishop of Derby as preacher.

The parish church of Bretforton, in the Vale of Evesham, was opened on Saturday on the completion of internal restoration carried out by Mr. Alfred Crisp, a local builder.

Our Office Table.

A SERIES of lectures on art, delivered under the auspices of the Corporation of Glasgow, was inaugurated at the Corporation Galleries in that city on Saturday evening. Bailie Bilsland presided, and there was a crowded attendance. Mr. John M. Gray, curator of the National Portrait Gallery, Edinburgh, gave the opening lecture, his subject being "Sir Henry Raeburn and Portraiture in Scotland." In the course of his paper Mr. Gray traced the rise of Scottish portraiture, and exhibited photographs showing examples of the earlier masters. Referring to Raeburn, he said that that artist in some respects was fit to rank with the masters of the olden time. He was, however, a good-natured, genial man of the world, who did not allow art to absorb his whole attention. Raeburn was a great painter, one felt, but a great painter who might easily have been greater. At the same time, the only Scottish painter fit to be mentioned in the same breath with him was David Wilkie.

A SUGGESTIVE anecdote illustrating the extent to which protection of native labour is carried in the Eastern States is told in the *New York Sun* concerning an artist, a member of the National Academy of Design, who had undertaken the decoration of a private residence. He engaged a fellow-artist and Academician to paint pictures on the walls of one of the rooms. While this painter was at his task a walking-delegate came up to him, and this colloquy occurred: "Do you belong to the union?" "What union?" "The fresco-painters' union." "No; I am not a fresco-painter—I am an artist." "Well, if you don't join the union, I shall order out every man at work in the house." Under that threat, and for the sake of his fellow-artist who had given him the commission, the artist was forced to join the union, pay the dues, and put himself under the authority of the walking-delegate as an artisan!

THE London County Council have applied to the Home Secretary, under section 12, subsections 3 and 5, of the Housing of the Working Classes Act, 1890, for permission to erect artisans' dwellings on the vacant plot of land on the Goldsmith-square site, suitable for the accommodation of the people displaced by the carrying out of the Boundary-street scheme. The Act provides that the Council may engage with any body of trustees, society, or persons to carry the scheme for the erection of dwelling-houses into effect, but the Council itself may not, without the express approval of the Home Secretary, undertake the rebuilding of houses. If sanction is obtained, specifications and estimates will be submitted, and thereafter building operations will be proceeded with. The Council must in terms of the Act sell and dispose of all such dwellings within ten years from the time of their completion.

TEN years ago, according to a Government return just published, the woodland surface of Great Britain was computed at 2,458,000 acres. By 1888 the acreage thus occupied had risen to 2,561,000 acres, and the measurements taken in 1891 show a further advance to 2,695,000 acres. Of the 134,000 acres thus added to the approximate woodland area of Great Britain, 96,000 acres are assigned to England, 31,000 acres to Scotland, and 7,000 acres to Wales. The largest woodland area to be found in England is the county of Hampshire, with 122,574 acres; Sussex with 122,073 acres, comes second; while the four counties of Hants, Sussex, Surrey, and Kent possess between them nearly a fourth of the English woods and plantations. These four counties have upwards of 11 per cent. of their surface thus occupied. In Scotland, Inverness-shire has no less than 169,000 acres of woodland, that being the largest area of woodland in Great Britain.

In conjunction with the Sanitary Institute, the Carpenters' Company have arranged a course of six lectures, specially adapted for candidates preparing for the examinations in practical sanitation and building construction, to be given in the hall of the company, London-wall, at 8 p.m. on November 18, 23, 25, and 30, and on December 2 and 7. The examinations are intended to be suitable for clerks of works, builders' foremen, and others who have to deal with the construction of buildings. Each

examination will occupy part of a Friday and Saturday. On the Friday the examination will last four hours—from 5 to 7 p.m. and from 7.50 to 9.30 p.m., and consist of written papers only. On the Saturday the examination will commence at 3 p.m., and be *viva voce*, with one or more questions to be answered in writing, if deemed necessary. No one under 21 years of age will be admitted to the examination. The first of the six lectures mentioned will be by Sir Douglas Galton, and the others will be delivered by Professor H. Robinson, Professor Banister Fletcher, Professor W. H. Corfield, Professor T. Roger Smith, and Mr. Henry Law.

ON Saturday last an examination of plumbers in the practice and theory of their craft was held in the Technical School, Manchester, with a view to testing the fitness of the candidates to receive the certificate of the Worshipful Company of Plumbers. The examiners present included Mr. John Holden, F.R.I.B.A., president of the Manchester District Council, and as representing the Worshipful Plumbers' Company; Mr. G. B. Davis, R.P., and Mr. Fred Scott, secretary. The practical test consisted in working up a 4in. break with inner and outer angles in 6lb. sheet lead, joining a piece of bent 2in. pipe into a piece of 4in. pipe, and an underhand soldered joint of two pieces of 3in. pipe. Time allowed 3½ hours. The written work consisted in answering ten questions supplied by the Plumbers' Company relating to the nature and uses of materials dealt with, the theory of hot and cold water circulation, the action of water and acids on lead, &c., some technical terms, choice of sanitary appliances, &c. There were 17 candidates in attendance, and out of these 13 satisfied the examiners, who stated that the average efficiency was much higher than usual.

The Architectural Association, 9, Conduit Street, W.; and 58, Great Marlborough Street, W.

THE ARCHITECTURAL ASSOCIATION COURSES OF LECTURES, CLASSES, and STUDIO INSTRUCTION are now commencing.

The Courses are both Elementary and Advanced, and are designed to provide a sound professional education, supplementary to that to be obtained by the prevailing system of pupillage. The Course, which is in four divisions, is progressive and consecutive, and the instruction is given by Lecturers and Instructors of known ability.

DIVISION I.

LECTURES and CLASSES.—The Orders of Greek and Roman Architecture, Building Materials, Perspective, Physics.

THE STUDIO.—Drawing from Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Plane Geometry, Criticism Meetings.

DIVISION II.

LECTURES and CLASSES.—English Architecture, Materials, Elements of Ornament and Colour Decoration, Strength of Materials, Stresses and Strains.

THE STUDIO.—Designs based upon Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Solid Geometry, Criticism Meetings.

DIVISION III.

LECTURES and CLASSES.—The History of Architecture, Materials, Colour Decoration, Sanitary Science as applied to Drainage and Water Supply.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Perspective and Sciography, Constructive Masonry, Criticism Meetings.

DIVISION IV.

LECTURES and CLASSES.—The History of Architecture; Sanitary Science—including Ventilation, Lighting and Heating, Painting, Sculpture; other Arts allied to Architecture; Professional Practice—including Legislative Enactments relating to Building Contracts.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Drawings of Ancient Buildings from actual measurement, Graphic Statics and Perspective, Criticism Meetings.

EXTRA SUBJECTS.

LECTURES and CLASSES.—Plane and Solid Geometry, Geology, Mensuration, Land Surveying and Levelling, Chemistry of Building Materials, Quantity Surveying—including the Preparation of Estimates, Discussion Section.

THE STUDIO.—Sketching and Measuring, Elementary Water Colour Class, Water Colour Class, Modelling.

A Pamphlet, containing full particulars of the curriculum, may be obtained free on application to the Hon. Sec., at 58, Great Marlborough-street, London, W. Fees must be paid in advance, and passes may be obtained at the Offices of the Association, between Ten a.m. and Seven p.m.

ERNEST S. GALE,
P. T. W. GOLDSMITH, } Hon. Secs.

The ceremony of laying the memorial stone commemorating the restoration of Dunblane Cathedral was performed on Friday by the Grand Master Mason of Scotland, the Earl of Haddington. The work of restoration has occupied three years. The nave, which stood roofless for 300 years, is now fitted to seat a congregation, and is lighted and heated. The work has cost £26,000. The architect is Dr. Rowand Anderson, of Edinburgh.

The work of founding a new watering-place between Lytham and St. Anne's, to be called "Fairhaven," is rapidly progressing. There are to be 15 streets and a marine lake 2½ miles long. Most of the former are within St. Anne's local board district, and three-fourths of the lake will be within the boundary of the Lytham Commissioners. The carriage drive will be 60ft. wide, and the footway 12ft. wide, besides which there will be an outer carriage drive formed on the Stanner Bank.

Trade News.

WAGES MOVEMENTS.

THE LONDON SCHOOL BOARD AND CONTRACTORS.—At the last meeting of the London School Board a deputation from the London Building Trades Committee waited upon the Board to present a memorial having reference to the conditions of the contracts entered into by the Board. Mr. Daw (secretary), who headed the deputation, stated that they represented the whole of the building industries of London. They wished the Board to consider the advisability of amending the fair contracts resolution made by the late Board to read as follows:—"That all contractors shall be required to sign a declaration that they are prepared to pay their workmen the recognised rates of wages, and to strictly observe the recognised rules and customs which prevail in the various trades as to the hours of labour." They asked the Board to prohibit subletting and piecework, and suggested when possible all labour should be employed direct from the Board without the intervention of a contractor. The members of the deputation answered a number of questions, and the memorial was then referred to the Works Committee.

DIRECT TENDERING BY TRADES UNIONS.—A special meeting, convened by the Street Masons, Paviers, Stone Dressers, and Hammermen's Amalgamated Union, was held on Monday at the Crown, Clerkenwell-green, to consider whether the Union should tender for the paving work of the Rotherhithe vestry. The chair was occupied by Mr. J. Madden, who explained that the Union had been invited to tender for the work by the vestry officials, the latter agreeing, in the event of the Union's tender being successful, to advance money from week to week to enable them to carry on the work. In the discussion which followed, attention was drawn to the co-operative quarries in Scotland, which are being worked by a Union very successfully. It was unanimously decided to tender for and undertake the work.

Among the adjudications in bankruptcy announced in Friday's *Gazette*, the name appears of Alfred Hood, of Bethnal-Green-road, builder and contractor.

In the case of Benjamin Beesley Booth, of Norton Woodseats, Derbyshire, builder, contractor, brick manufacturer, and quarry owner, trading with William Camm Wilson as Wilson and Booth, the discharge from bankruptcy has been refused.

A stained-glass window, designed and executed by Mr. C. E. Kempe, of London, has been placed at the end of the chancel of the North Luffenham church. The scenes represented are the Crucifixion of our Lord and the principal events of St. John Baptist, the patron saint of the church.

The first annual dinner of the recently-formed Rugby Building Trades Council was held last week in a local hall under the chairmanship of Mr. J. MacGawley, the president.

Stenton parish church, N.B., was reopened on Sunday, after restoration. The church, which is a Gothic edifice, with tower, was erected in 1829 from designs by Burn, and was opened in that year by Dr. Chalmers. The pulpit has been removed to the south-west corner, the pews have been lowered and widened, the walls repainted, and the whole congregation now facing the minister. On the platform are placed the Communion table, font, and lectern, as also the harmonium. A stained-glass window has been placed in the north side of the church, and the other windows have been filled with tinted glass, all having been executed by Messrs. A. Ballantine and Gardiner, Edinburgh. The architect was Mr. James Jerdan, George-street, Edinburgh.

The Khedive opened, at Alexandria on Monday, the new museum of Græco-Roman and Early Christian Antiquities and the Municipal Library. These institutions have been founded, not only for scientific purposes, but also with the view to inducing tourists passing through the city to make a short stay there.

Mr. Somers Clarke, F.S.A., is the architect of the chancel of the Parish Church, Brighton, and the works are about to recommence forthwith. The foundations and crypt cost over £3,200, and the structure has been at a standstill for some time owing to want of funds. The church, formerly known as St. Peter's, was a famous building in its day as the design of Sir Charles Barry, R.A.

The Rural Sanitary Authority at Barton, Manchester, have decided to make application to the Local Government Board for sanction to borrow £16,500, to be repaid in 40 years, for works of main drainage and sewage disposal at Irlam and Cadishead. For the present it is proposed to execute works estimated to cost £10,194. The scheme has been prepared by Mr. C. C. Hooley, C.E., surveyor to the authority.

CHIPS.

The Derbyshire County Council have increased the salary of Mr. R. C. Cordon, their district surveyor for Mid-Derbyshire, from £130 to £150 per annum.

Alterations have been made to Ballybot Court-House, Ireland, and special attention has been paid to the ventilation, the extraction of the vitiated air being effected by Messrs. Robert Boyle and Sons' latest improved patent self-acting air-pump ventilator.

The spire of St. Barnabas's Church, Parliament-street, Liverpool, being in a dangerous condition, is being taken down by Mr. T. C. Ebdy, of North John-street, the architect to the trustees. The whole church is shortly coming down, and the stone and material will be used in building a church in the Anfield district, to accommodate about 700 persons.

At Dundee the operative plumbers have threatened to withdraw from the practical plumbing class established by the Technical Institute unless the names of three young men, described as tinsmiths, be taken off the roll. They claim that none but qualified plumbers or plumbers' apprentices shall be admitted to avail themselves of the classes.

The Baptist chapel at Elenbridge, Kent, was reopened on Wednesday week after enlargement, the erection of a new frontage, and external decoration. Mr. Hooper was the architect, and Mr. Abbott the builder.

The North Bierley Joint Fever Hospital was formally opened on Saturday. The hospital is for the use of the inhabitants of the local board districts of Cleckheaton, Hunsworth, North Bierley, and Tong. The district is 9,769 acres in extent, and the population is 42,299. The buildings comprise an administrative block; a ward pavilion, with twelve beds and six cots; an isolation block, with ten beds and four cots, besides wash-houses and sheds.

The new schools of the Hebburn School Board are being ventilated on the Baird-Thompson system, their latest improved exhaust roof ventilators and air inlet ventilators being introduced throughout. The same is also being applied to the Oldham schools.

On Friday Colonel Ducat, R.E., Local Government Board inspector, held an inquiry at the Town hall, Tamworth, with respect to applications by the town council for a loan of £1,000 for street improvements, and by the urban and rural sanitary authorities for a joint loan of £2,250 for the purchase of the Castle Mill and its weirs, to prevent flooding.

The new buildings erected by the Glasgow Workmen's Dwellings Company, Limited, at Cathedral Court, Rotten-row, near the corner of High-street, were publicly opened on the 12th inst. by the chairman of the company, Sir James King. This is an experiment block of model dwellings for the working classes, erected from the designs and under the supervision of Mr. John James Burnet (of Messrs. John Burnet, Son, and Campbell, architects), at a cost of about £8,000.

On Saturday last Mr. W. Terrill, late assistant borough surveyor of Maidstone, who was some time ago appointed surveyor to the local board of Ashford, was presented at the New Inn Hotel, Maidstone, with an ivory pocket rule and a pair of compasses, together with an illuminated address, by Mr. Scoones, borough surveyor, on behalf of the employés of the Maidstone Corporation.

Holloway's Ointment—With catarrh, coughs, and influenza everywhere abounding, it should be universally known that Holloway's Ointment, diligently rubbed upon the chest, checks the worst assaults of these maladies, and secretly wards off more grave and dangerous diseases of the throat and lungs. The truth of this assertion must remain unquestioned in the face of thousands of unimpeachable living witnesses.

CRAIGLEITH STONE.

UNEQUALLED for Staircases, Steps, and Landings, especially for Public Buildings with great wear. VERY HARD, and NEVER WEARS SLIPPERY.

SOLE AGENTS for England,

J. & A. CREW, Cumberland Market, London, N.W.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—T. PETTITT and CO., Lithographers, 28, Fritch-street, Soho, London, W. Established 50 years.

DOULTING FREESTONE.

THE CHELYNCH STONE—The Stone from these Quarries is known as the "Weather Bed," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMLEDITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to CHARLES TRASK and SONS, Doulting, Shepton Mallet, Somerset. London Agent:—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—

THE HAM HILL STONE COMPANY

NORTON, STOKE-UNDER-HAM, SOMERSET.

Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C.

WM. OLIVER & SONS,
MAHOGANY, WAINSCOT, WALNUT,
TEAK, VENEER, and FANCYWOOD
MERCHANTS,

120, BUNHILL ROW, LONDON, E.C.

The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

ASHBURTON.—For sundry alterations and renovations to the Congregational Church, Ashburton. Messrs. G. S. Bridgman, M.S.A., and Norman G. Bridgman, A.R.I.B.A., Torquay and Paignton, architects:—
Pomroy, J. Ashburton £230 0 0

ASTON, BIRMINGHAM.—For the remaking of Rockylane, and the reconstruction of the bridge over the canal, for the Aston local board:—
Jones and Fitzmaurice (accepted) ... £3,052 0 0

BEDMINSTER, BRISTOL.—For alterations and additions to Whitehouse-street Tannery, Bedminster, for Messrs. Parker Bros. Limited. Mr. Herbert J. Jones, architect:—
Perrott, J. £1,815 0 0
Bastow, J. 1,900 0 0
Cowlin and Son 1,892 0 0
Church, W. 1,740 0 0
Gay, E. 1,707 13 0
Wilkins, G. H. 1,690 0 0
Eastbrook and Son (accepted) ... 1,670 0 0

BANSTEAD.—For building detached house at Banstead, Surrey. Mr. Frederick W. Ledger, 3, Lombard-court, E.C., architect. Mr. William Burrell, 9, Adam-street, Adelphi, W.C., surveyor:—

Woodward	£2,290 0 0
Bryant and Son	2,175 0 0
Smith, J.	2,047 0 0
Notley, W.	2,020 0 0
Gregory	2,000 0 0
Potter	1,995 0 0
Nightingale, B. E.	1,985 0 0
Mills	1,956 0 0
Adams	1,933 0 0
Reynolds	1,876 0 0
Taylor, M.	1,807 0 0

BERMONDSEY, S.E.—For providing new hot-water apparatus at the Rolls-road School, Bermondsey, for the London School Board:—

Cannon, W. G.	£399 0 0
Crane, R.	388 0 0
May, J. and F.	353 0 0
Davis, G.	347 0 0
Russell and Co.	339 0 0
Purcell and Nobbs	337 0 0
Bacon and Co.	309 10 0
Kinnell, C. F., and Co., Southwark-street, S.E. (accepted)	275 0 0

BERMONDSEY, S.E.—For reconstructing the drains at Alexis-street School, Bermondsey, for the London School Board:—

Goad, W. V.	£1,250 0 0
Tyerman, J.	1,100 0 0
Marsland, J.	1,025 0 0
Holloway Brothers	920 0 0
Smith, J., and Sons	895 0 0
Whitehead, L., and Co.	895 0 0
Downs, W.	855 0 0
Leeks and Hooker, Webber row, S.E. (accepted)	776 0 0

BRISTOL.—For the erection of the central electric lighting station and chimney stack for the city council:—
Hayes, C. A., Bristol (accepted) ... £13,346 0 0

BRIXHAM, S. DEVON.—For the erection of two shops and dwelling-houses, The Beach, Brixham. Mr. G. S. Bridgman, M.S.A., and Norman G. Bridgman, A.R.I.B.A., Torquay and Paignton, architects:—
Hosgood and Spark Brixham ... £577 0 0

CHELSEA, S.W.—For providing a new main and six additional radiators on the top floor of the girls' department of the Everington-street school, for the London School Board:—

Fraser, J., and Son	£145 12 0
Cannon, W. G.	90 0 0
Purcell and Nobbs	87 15 0
May, J. and F.	85 0 0
Berry and Sons, Regency-street, Westminster (accepted)	74 0 0
(Estimated cost, £95.)	

CLAPHAM JUNCTION, S.W.—For converting the private dwelling-house, No. 34, Northcote road, into a shop. Mr. M. V. Treleaven, Acre-lane, Brixton, architect and surveyor:—

Clarke	£523 0 0
Sommerford and Son	521 0 0
Maxwell, Limited	444 0 0
Sumner	442 0 0
Smart and Son	398 0 0
Rice and Son	375 0 0

CRADLEY HEATH.—For new house, Cradley Heath, Staffordshire, for Mr. John Fellows. Mr. A. T. Butler, architect:—

Cope, H., jun. (accepted)	£1,025 0 0
---------------------------	------------

DEPTFORD.—For taking down and rebuilding stables and granary at the rear of 103, High-street, Deptford, S.E., for Mr. Jas. Murray. Mr. John Jas. Downes, 11, The Parade, Lewisham High-road, S.E., architect:—

Soper, R.	£1,590 0 0
Wilson, A.	1,510 0 0
Leng, T. D.	1,138 0 0
Lorden, W. H., and Son	997 0 0
Best, S. R. (accepted)	924 10 0

DEPTFORD.—For repairs to Normandy Wharf, Ravensbourne-street, Deptford, S.E., for Mr. W. C. Mockford. Mr. John Jas. Downes, 11, The Parade, Lewisham High-road, S.E., architect:—

Wilson, A.	£195 15 0

THE BUILDING NEWS AND ENGINEERING JOURNAL.

VOL. LXIII.—No. 1973.

FRIDAY, OCTOBER 28, 1892.

SHOULD ARCHITECTS TAKE OUT THEIR OWN QUANTITIES?

ALTHOUGH this question has been frequently the subject of controversy in these columns, no general agreement has been come to. A large number of architects in provincial towns, as well as in London, still contend that the practice of taking-out quantities for their own work is justified by various considerations of a practical kind: First, that an architect being the designer, knows better than anyone else the requirements of a given building, that he alone is competent to decide what should be included in the items submitted to the contractor, and that, being master of the situation, he is able to determine how much or how little of certain materials should be used, and the mode of measurement to be adopted. Moreover, as he is to be judge of the work, and has to determine its construction, it is argued that the employment of a surveyor, who has to obtain his instructions from the architect, cannot possibly facilitate the business, but must rather cause unnecessary friction. These are reasons which appear to weigh considerably against the objections raised on the other side—namely, that an architect should be entirely free from any participation in the commercial part of the contract, and that he ought to hold himself independent of any obligation to the builder. We do not underrate the force of either of these contentions. Recent discussions that have taken place in the profession as to what constitutes the qualifications of an architect have unquestionably aggravated the situation by increasing the breach between the architect and surveyor.

For many years the two professions have lived in harmonious union—whether the happiest or not we will not say. But of late the apple of discord has been thrown amongst them; the term “business architect” has been flung as a reproach against all those who have been making a remunerative living by taking up surveying work. The functions and duties of the surveyor have become more definite, the Institution of Surveyors have been increasing and strengthening their bonds of membership, and in various ways the unity of the two professions have been destroyed. It was almost natural that this rupture should take place. A process of disintegration, which will end no one knows where, has been going on. On the other side we have those who make the claim of art paramount, and who steadfastly refuse to believe that architecture can in any way be joined to businesses that had never till lately had any connection with her. The very name of “profession” they abhor. We may call the reader's attention to the recent book of essays edited by Mr. T. G. Jackson, A.R.A., and Mr. Norman Shaw, R.A., to show the strong and growing feeling among architects to dissociate themselves from those who combine a variety of vocations, and who employ a large staff of assistants. Mr. Jackson draws attention to the ordinary professional architect “who does not meddle much with art, but acts as a middleman between his employers and the carver, the glass painter, and other working artists whose ideas he adopts as his own.” The architect who undertakes quantities and makes valuations of property is likewise tempted to make his professed art a secondary matter, and to confine his attention to that branch which pays the best. All this is reprehensible. We have before now

referred to architects who obtain their designs of woodwork and fittings from special artists and make them their own, or who use trade-catalogue designs instead of making details. Now, the man who prepares his own quantities must naturally have a strong inducement to adopt stock patterns, or to take what the wood or metal-worker gives him. The idea of reducing cost is ever before him, and he is glad to consult the artist-craftsman as to how any part of the details and fittings of a building may be cut down. Quantities, no doubt, have much to answer for the “Ghosts of the Profession,” which Mr. Prior has essayed about. They have been conjured up and requisitioned by men who find “quantities” more lucrative than art.

The preparation of quantities by an architect has no doubt other tendencies calculated to prejudice architectural design, as for example in the system of repetition and duplication of features and details. A man who designs a building and has the “quantities” staring him in the face is more likely to use the greatest care in avoiding expensive features and in arranging his details so that his windows, and cornices, and dressings may agree. To take one example of a building in which the windows are constructed of terracotta. They may be a number of bay windows of ornamental character. The art architect, independent of cost considerations, would design each, and its details, with relation to the position or connection with other features. The details at least would vary: one window might be wide, another narrow; the mullions would be differently spaced to suit the rooms or to give variety to the façade. The relief or enriched panels would be varied, and the mouldings would be different; but the practitioner who took out his own quantities would most likely make the bay windows the same in projection, width, and detail to save modelling, and each piece measured per foot cube would be numbered in the bill according to the number of windows. The advantage of this, both in “taking out” the quantities as well as in saving cost and labour in setting, would be very evident, though the design would undoubtedly lose in its individuality and artistic variety. The same inclination to repeat one design of panel, or moulding, or internal fitting is one of the strongest of the motives of the expert quantity surveyor. It saves an immense amount of labour in measuring, abstracting, and billing, and in cost of execution as well.

The last advantage is one of the strongest pleas put forth by those who think that quantity taking is a duty of the architect. He is less likely to be extravagant by cutting down what is unnecessary. But may not this very process be carried too far? May it not lead to a kind of cheese-paring economy inimical to good architecture? Has it not been the cause of that skin-deep sort of ornament which passes muster for art, the overlaying a plain and irredeemably bad building with just a thin veneer of pilasters, panels, and dressings?

The practice of taking out quantities—a lucrative one amongst many provincial practitioners—is also, no doubt, detrimental to the independence which the architect should have as an arbitrator; but this is a point on which we need not dwell here. It is rather more the question of forming another division within the profession that we have in view. There is a strong integrating action going on which the profession ought to watch. Some of the leaders of that profession can very well see the drift. It has been said lately that there is a tendency to develop the muscular part of the profession in the civil engineer, the lucrative, monetary part in the quantity surveyor, while the architect proper will be left to pick up what he can. Legislative measures, it is said, will encourage this disintegration or division. We answer that it exists now in

a more pronounced form than it would if there was a bond uniting the qualifications. The intelligent, discerning part of the public know where they can obtain the services of a real architect—one who knows how to design artistically—he is known by repute; whereas the others fall by a sort of “natural selection” into their places as surveyors or technical experts, and to a large degree this kind of separation or segregation will always exist in every profession. There will always be those who take up wrong vocations, and who find some one branch more remunerative than another. So it is with many who join the business of quantity-taking to that of architecture; they find it pays better, but they unfortunately expose themselves to the retort that their architecture is of a somewhat feeble and indifferent kind.

OPENINGS FOR THE ART-WORKMAN.

IF there is one thing beyond all others which we do not mean by the art-workman, it is the mere ornamentist. There have been too many openings for him already, and he has availed himself of them a great deal too much. It is the very misery of the age that the infinity of ugliness it produces is not the naïve, unaffected ugliness of work done to supply pressing practical wants; too pressing to let the worker look beyond them. It is an ugliness dressed up, tricked out, and emphasised by trashy decoration: an ugliness which cannot lie quiet, but which shouts and screams for all the world to look at it. Such ugliness as this one can never, in these days, keep far away from. The city streets are full of it; in the suburbs it stares from every house, and, worst of all, there is no escaping it, even in one's home. How much longer shall we have to bear it? When will the artist come?—when will the ornamentist go?

Things have come to such a pass that in some trades nothing can be bought without ornament except at a high price as a special luxury. Try, for instance, to buy a cheap stove fit for a cottage. You choose the plainest pattern you can see, and find it twice or thrice as dear as, for practical purposes, it need be. You ask for something less expensive, and you are shown a dozen alternative designs, hideous in form, but covered with ornament like a cutaneous eruption. In shape they would disgrace the lowest savage; but in decoration they seek to vie with the richest of Classic and Renaissance architecture. One moulding is cut up into eggs and tongues; another is formed into a *guilloche*, the rest are covered with carvings, or rather, castings, equally ambitious, for which the ironfounder only can supply a name. Acanthus-leaves diversify the flat surfaces, and pleasingly combine with Gothic diapers, taken, perhaps, from Westminster Abbey. That is the popular notion of a cheap stove. That is a result—though, happily, not the only or the highest result—of Government art-education, carried on for nearly half a century. We do not forget such schools of art as the Lambeth one, which has invented new types of design, and has turned out work as genuine as that of any age or any nation. But it is to the inferior schools of art, and to inferior pupils at the good ones, that we owe a multitude of the “ornamental” abominations of the period. A young man enters them; he sees his fellows all employed on drawing ornament, modelling ornament, designing ornament; and, unless his taste and judgment are above the average, he concludes that ornament is the one thing needful. Then he goes out into the world and applies it. He knows nothing about general form. He is incapable of shaping anything. All he can do is to cover the stock-shapes with ornament, as a whitewasher covers walls with whitewash. Having done this, he

thinks himself an artist; and his employer calls himself an art manufacturer.

Here, then, is an opening for the real art workman. Stoves are bought and sold every year by scores of thousands. A man with any taste or sense of fitness can hardly ever find a stove that does not disgust him, unless he pays a disproportionately high price for it. Except on those terms, he can get nothing that is plain, though he can get everything that is ugly. Why does not some one bring into the market a few designs of unpretending general form, free from attempts at "enrichment"? A village blacksmith, left to himself, could make a stove by which an artist would sit day after day without perpetually longing to smash it. Why cannot the caster of iron do something equally unobjectionable? Why cannot he also find out what shapes suit the nature of his material, and adopt them? Unfortunately, he has hardly begun to do this yet—or, to speak more exactly, he has long since forgotten the way.

If there is anywhere a person in blank ignorance of art, that person is the average ironfounder. Walk through Thames-street, and look at his productions! His pattern-books are an abomination, his show-room is a chamber of horrors; his life is passed in showing everyone who works in metal how not to do it. The forms he adopts belong to every material except his own. When he is very ambitious, he mimics the stonemason. Then he turns out cast-iron tracery, and cast-iron crockets, and cast-iron pinnacles; or he gives you a Corinthian capital, with the leaves cast separately, and stuck on for a little while, by pins or screws. In a humbler mood, he imitates the joiner. Now he offers you a grate with stop-chamfered bars, in which all the ends cross each other, as if they were halved together. But his chief delight is to copy the smith in his most characteristic effects. He prides himself especially on this, and offers you what he calls "the same thing at less money." If the smith hammers a scroll, he can cast one, and he can cast, also, an imitation of all the sharp angles and thin plates or leaves which are natural to wrought work, and absurd in any other. That is about as far as the ironfounder usually gets. He is a kind of art-parasite, living on other men's ideas, and unfortunately for himself on ideas that do not agree with him. Of late years his business has fallen off. His productions have grown a little too bad for an age which, by slow degrees, is getting back its sense of beauty, and the orders which used to go to him have gone to the wrought-iron worker instead. He thinks, poor man, that this is only a change of fashion. It does not occur to him that by any effort he could prevent it. He has tried aping masonry, and joinery, and smith's work, and he cannot see that there is anything further to be done. To develop art in cast metal itself is too wild a project for him to attempt. Here, then, is an opportunity for the art workman. Here is a great manufacture waiting for him to transform it—waiting, and perishing as it waits, because he does not come.

Let us turn to another trade—that of the marble-worker. There is only one common object of daily life whose ugliness quite matches that of the ordinary stove, and it happens to be the object that goes along with it—the mantelpiece. Years ago marble mantelpieces were used everywhere; but the marble mason, like the ironfounder, had not the wit to move with the times. His productions got worse, as public taste got better, and so popular support, to a great extent, has left him. His sham pilasters, made up of thin slabs put together like boxes, were too silly a fraud to last, his sham consoles, stuck with plaster to the shelf they pretended to support, were too ugly to bear interminable repetition. People like marble,

in the abstract, for mantelpieces, but there is a limit to their endurance when it is so basely misused. They have given it up, therefore, and have made shift with wood instead—or even with iron copies of wood—which, bad as they are, are yet less strikingly offensive than the marble worker's stock patterns. But they are ready to come back if they can get marble in sensible shapes, not boxed out into gigantic blocks which nobody believes in, not stop-chamfered into carpenters' Gothic, not disfigured with imitation trusses of hideous form, turned out wholesale by machinery. Here is another trade wasting away for want of the art which its tradesmen cannot see the value of. Here is another opportunity crying aloud for the art workman.

Look again at plastering—internal and external—not the plastering of some cleverly-designed house, arranged by a competent architect; but that of the myriads of builders' structures, over which no architect has any control. Compare it with the plastering of country cottages, done a century or two ago, and see what a fall has taken place in the interval. Then plaster was used like plaster, and, used so, it has a beauty of its own. Its projections were slight, its lines were delicate, its surfaces had some texture—it might be of rough-cast, it might be of par-getting. Its design suited the conditions, and the work was at once beautiful and durable. Now, although plenty of good cement can be had, and although this is a harder and more durable substance than the lime and sand of olden times, it does not last half as long, because it is made up into forms which are not natural or suitable to it. It aims at too much projection in its cornices; it cannot be content with patterns in low relief; it wants to do all that can be done in stonework. This is no new complaint. For fifty years and more the misuse of plaster has been a subject for architectural writers. But it is with the plasterers as it is with the ironfounders and the marble workers. They cannot improve; they only sit still and see their work pass away from them; they do not lift a finger to retain it. So it comes to pass that, just as wrought iron has superseded cast iron, and wood has superseded marble, brick and terracotta have superseded, and are superseding, plaster. There are places still where it might well be used, but only art can save it; and the people who are most concerned do not know what art is, or what it would be worth to them in money. Not only in the three departments we have here noted, but in fifty others of minor importance, fortune and reputation are crying aloud for someone to come and take them. The ornamentist cannot do it; the adventure is reserved for his mortal enemy, the true art-workman.

THE SOCIETY OF ARCHITECTS.

THE first ordinary meeting of the Society of Architects for the present session will be held at St. James's Hall on Tuesday afternoon, Nov. 15, at 3 o'clock, when the President, Mr. Robert Walker, of Cork, will deliver an inaugural address. In the evening the members will dine together at the Holborn Restaurant.

The annual report of the Council, which will be submitted at the ordinary meeting in the afternoon, states that steady progress is being made by the society. Thirty-five new members have been made during the session, after very careful investigation into their qualifications, and two gentlemen of distinction have been added to the list of honorary members. One member has died, and there have been eight retirements from various causes, leaving a net increase of 27. The annual excursion took place in August, 1891, when an extended tour was made in Belgium by a party of 42. During the session, an address and a paper were read by the President, Mr. W. H. Seth-Smith, and papers were also read by Messrs. G. A. T. Middleton (secretary), Wyke Baylis, R. O. Allsop, Professor J. Logan Lobley,

A. Hands, Ellis Marsland, W. L. Bros, Ernest Day, and Rev. J. E. Field. The Council met twenty-two times, the Finance Committee eight times, and the Practice Committee eight times during the session, the last named body considering and reporting to the Council upon several important questions raised by members in consequence of difficulties arising in their practice. Advice has thus been several times given which has proved of value. In January a sub-committee was appointed to consider the proposed London Building Law Consolidation Bill. This sub-committee has met ten times, and has drawn up an exhaustive report and a set of suggested amendments to the Bill. These were adopted by the members at the annual meeting in June. The Council have given their support to the Architects' Registration Bill, and regret that the early close of the Parliamentary Session should have caused further delay in its consideration by the House; but trust that the Registration Act Committee, which has it in hand, may succeed in bringing it to a second reading during next Parliament.

THE ARCHITECTURAL ASSOCIATION.

THE inaugural meeting for the present session of the Association was held on Friday evening, the President, Mr. H. O. Cresswell, in the chair. The adoption of the annual report and balance-sheet was moved by Mr. F. T. BAGGALLAY, ex-president, who said the result of the year's working of the new scheme was better than they had a right to expect. The motion was seconded by Mr. HAMPDEN W. PRATT, and agreed to. A cordial vote of thanks was passed to the entertainment committee, with especial mention by the President, who proposed the motion, of the services of Mr. A. W. Earle, the secretary, for the arrangements for the recent *conversazione* at the Imperial Institute. Forty-six nominations for membership were read, and the following three new members were elected: H. R. Macaulay, K. Oldham, and L. Banks Price.

PRIZE LIST.

The PRESIDENT then announced the winners of the prizes for last session as follows:

THE A. A. TRAVELLING STUDENTSHIP.—Bronze medal, T. A. Sladdin. Second prize of £5, E. A. Rickards.

THE ASSOCIATION MEDAL, with a Prize of £10 10s.—A. H. Clark. Second prize of £5 5s. (special), A. H. Moore. Hon. mention, W. A. Forsyth.

THE DISCUSSION SECTION PRIZE.—First prize, not awarded. Second prize of £1 1s. (special), J. C. Stockdale.

THE ARTHUR CATES SCHOLARSHIP.—W. E. Waymouth.

MEASURED DRAWINGS PRIZE.—A. J. Roddis.

THE ANDREW OLIVER PRIZE.—First prize (£3 3s.), not awarded. Second prize (£2 2s.), A. Stratton.

Lecture Side.—First year: Silver Medal, F. S. Hammond; Bronze Medal, G. E. Boys; Hon. Mention, E. Tylee. Second year: Silver Medal, C. C. Brewer; Bronze Medal, J. R. Stark; Hon. Mention, R. H. Hunter. Third year: Silver Medal, P. R. Smith; Bronze Medal, A. J. Johnson; Hon. Mention, W. K. Shirley.

Studio Side.—First year: Silver Medal, R. F. Summers; Bronze Medal, E. O. Cummins; Hon. Mention, E. G. Simpson. Second year: Silver Medal, J. P. Clark; Bronze Medal, A. Stratton and F. Taylor; Hon. Mention, C. C. Brewer. Third year: Silver Medal, C. C. Winnill; Bronze Medal, W. C. Waymouth; Hon. Mention, A. T. Walmisley.

The PRESIDENT said he regretted to announce the decease of Mr. James Fowler, of Louth, an old and valued member of the Association, and one who took a genial and prominent part in the annual excursions. It was agreed to send a letter of condolence to the widow.

Mr. E. S. GALE, secretary, proposed a vote of thanks to Mr. James Brooks for his promise of a prize of ten guineas for the best set of measured drawings of the choir of Oxford Cathedral.

THE INAUGURAL ADDRESS

was then delivered by the PRESIDENT. He remarked that his first duty was to render some account of the result of the first year's working of the new educational scheme. Speaking generally, that result was a very satisfactory one, amply justifying the expectations of those who took a prominent part in its inception, and spared no pains in working out the numerous details. They might congratulate themselves on the fact that though they had had many critics, representing as many different shades of opinion, their criticisms had been chiefly directed to matters of detail, while they had generally approved the scheme as a whole. Taking the Classes and Lectures first, the total number of full students who joined the first year's course was 30. In

addition to these there were a certain number of occasional students, who did not take the whole, but joined only certain classes and lectures. The number of these varied in the different subjects, but the largest number in any one class was 20, and this was in the Lectures on Materials and Construction. In the second year there were eight full students taking the whole course, and of occasional students the largest number attending any one class was ten—in the class for the study of Ornament and Colour Decoration—"English Architecture" coming next with nine. In the third year there were nine full students, and the largest number of occasional students was eight, in the class for Specification Writing and Quantity Taking. It had been intended to start a fourth year course if sufficient students sent in their names, but as the number of these was not large enough to justify the committee in doing so, that course was not held on the Lecture side. There was no need to be discouraged on that account, as it was both natural and advisable that the men should start in the earlier courses, and work up gradually to the more advanced ones, so that as long as there was a steady supply of students coming in at the bottom they would have plenty to fill the classes at the top in future years. Turning to the Studio side, the proportion of students in the junior years, as compared with the senior, was very similar to that in the lectures and classes. Thus, in the first year there were fourteen full students and seven occasional students, in the second year five full students, and five occasional students, and in the third year ten full students and eight occasional students. In the fourth year the Water Colour Class was attended by seven students, and the Discussion Section, which was practically the old Advanced Class of Construction, was as popular as ever. Considering that the Studio was an altogether new departure in the Association, the result was very gratifying, and showed that it supplied a real need which had been appreciated by the students. Coming to the financial side of the question, the result of the first year's working was more satisfactory than the committee had at one time anticipated. The scale of fees payable by students was arranged with the intention of making the scheme self-supporting. The committee expected, however, that for the first year or two the number of students would be insufficient to enable them to meet all expenses out of the fees received. This had proved to be the case, for although on the first and second years they realised a profit, this was all swallowed up by the loss on the third and fourth years, leaving a loss of something like £200. This statement of their financial position was not, taking into account the capital expenditure, necessitated by the alterations to the new premises, and the outlay in furnishing and equipping the Studio and class-rooms to fit them for the work to be carried on. This had been treated as an outlay of capital to be met by special donations from members and others interested in the Association. The amount received in donations to the general fund up to the present time was about £1,000. The President accorded a tribute of praise to the lecturers and instructors who had contributed so much to the success achieved up to the present. The Association was to be congratulated on having found such an able body of men to conduct its classes and lectures. Acting on the suggestions made by the lecturers and instructors, as the result of the session's working, several changes suggested by examiners had been made in the arrangements. This work was now classed under four divisions, instead of as many years, and a system was adopted by which a student could exchange any given subject in one of these divisions (within certain restrictions) for the corresponding subject in any other division. The duration of the lectures and classes was reduced from one and a half each to one hour each, except in the studio, where the work was not so exciting while it lasted. In order also to reduce the work included in each year's course, which was admittedly too heavy, a certain number of subjects both on the lecture and studio side had been classified as "extra subjects." That was to say, that without omitting any of the subjects from the curriculum altogether, they divided the subjects into two classes, those which the committee considered absolutely essential, and those which they considered as being only desirable. Arrangements had been made by which each student who paid an inclusive fee, either in the studio or classes, might also take up any one of these extra subjects each year without any

extra fee. The changes in the staff included the retirement of Mr. Schultz and Mr. Prioleau Warren, on account of the stress of business engagements, in whose stead Mr. W. G. B. Lewis had been appointed to the junior division, and Mr. J. D. Crace as instructor of the class of colour decoration. The President continued: The success of last session was all very well as far as it went; but it does not go nearly far enough, and we should like to see a much larger number of students working regularly in the classes this year than last. Out of a total of over 1,100 members, there were only 180 working regularly in the classes, or less than 17 per cent. of our total membership, which is a small percentage, considering the very large proportion of young men of which our membership is composed. Out of 100 new members who joined last session—almost entirely composed of pupils and assistants—only 54 availed themselves of the classes. Where are the other 46? After making all allowances for country members, and for men who had nothing more to learn—or thought so—we ought to have had at least 25 more men out of the 46 alone. I would draw the attention of the more senior members of this Association to some of the lectures which have been arranged for the fourth division, such as the courses upon painting, sculpture, and decorative art, for which we have been lucky enough to secure the services of such men as Mr. Stirling Lee and Mr. Walter Crane; also to the very excellent and comprehensive syllabus prepared by Mr. Edwin T. Hall for his three lectures on "Professional Practice." The President referred to the other means of instruction carried on in connection with the Association, first of which he placed the fortnightly meetings for the reading and discussion of papers, the visits to works in progress, and to old buildings, and the measurement of old work; he also called attention to the A.A. Sketch-Book and A.A. Notes, and suggested that the Essay Prize ought to be more keenly contested for than had been the case of late years. Turning now from the work of the students to matters of more general interest, I must, the President added, say a few words on the subject of the differences which marked the close of last session, and which at one time threatened to cause a serious split in our ranks. Although in the heat of the controversy much was said and much was written on both sides, which in calmer moments they would probably regret, yet wiser counsels have prevailed, and the good sense and moderation of both parties has shown them that by the exercise of a little tact and consideration for the opinions of others, each can learn something from the other, and that more good can be achieved by united action than by a blind and unreasoning hostility. I trust that all feeling of enmity has passed away, and that we shall have the cordial co-operation of all members for the welfare of the Association in the future, as we have in the past. At no time of its existence has this Association more needed the strength which is the result of united action, standing as we do on the threshold of a new departure in our history. Among the questions raised in the dispute were some of vital importance to this Association, and not only to this Association, but affecting interests of a wider range. In consequence of our having endeavoured to do something to systematise the course of study for architectural students, we have been accused of degenerating into a mere cramming ground for the Institute examinations. Cramming is the operation of forcing information into a man at high-pressure so as to enable him to acquire just sufficient to pass an examination in a given time, and is only necessary for those who have not availed themselves of the ordinary means of instruction. I hardly think that the term "cramming" can be properly applied to a course of instruction which is spread over at least four years, and which may be spread over a longer period still at the option of the student. The advice to students printed in last year's Brown Book stated that the course is expressly designed for the purpose of preventing the necessity for cramming, and the student is advised not to attempt to go through the whole course in four years, unless he is able to devote a certain amount of time in each week during the day for the purpose of reading books referred to in the various lectures and for private study. The term "cramming" is, therefore, altogether misapplied in speaking of the A.A. course of instruction. Then as regards the question of preparation for the Institute Examination. The primary object

we had in view in laying down the new curriculum was to afford an opportunity for acquiring instruction in those subjects which, coupled with the experience to be gained in an office, would fit a man for his work as an architect; but at the same time we felt bound to take notice of the examination tests imposed by such bodies as the R.I.B.A., the R.A., or other kindred societies for the admission of students to membership or to their schools, and had we not done so we should have failed in our duty to our students and to ourselves. Whether the Institute should or not impose an examination upon all those who desire to be admitted within its ranks is a question into which I do not propose to enter here. The point that we, as a teaching body, have to consider is the fact that the examination exists, and that many of our students come to us for the express purpose of acquiring the information in our classes or studio necessary to pass it. The student has perfect freedom of action, and if he desires to go in for the examination we believe that he can obtain all the information necessary in our classes; if, on the other hand, he does not wish to do so, he can take up as much of the course as he thinks necessary or suitable to the particular bent of his genius. Again, it has been said that, by accepting a contribution from the Institute towards our funds, we have sacrificed our independence, and handed ourselves over to that body bound hand and foot. I do not believe it, nor do I think that anyone else who knows anything of this Association or of the Institute would believe the acceptance of a grant implied any such thing. We are the best of friends, and I hope may remain so; but we, as an Association, are jealous of our independence. Self-help is one of our guiding principles, and self-government is inseparably connected with it; and though this Association has been in existence for nearly fifty years, I think it has reason to be proud of the fact that until last year it had never appealed to those outside its own ranks for pecuniary assistance, and it only did so then because it was endeavouring to found a scheme of education on a much wider and more comprehensive basis than had ever been attempted before, and which required a larger outlay of capital than it had at its disposal. But though the Institute responded generously to that appeal, it is not to members of the Institute alone that we are beholden for contributions to our funds. Among the list of subscribers are to be found such names as that of Mr. Norman Shaw, Mr. T. G. Jackson, Sir Arthur W. Blomfield, and others, gentlemen who are strongly opposed to the policy of the Institute, and who, for want of a better title, have been called the "Memorialists." We are equally beholden to these gentlemen for their assistance, but it is urged that by accepting their contributions we have sacrificed our independence, and handed ourselves over bound hand and foot to them also? The traditional policy of this Association has always been not to mix itself up in architectural politics at all, but to devote itself to the education of its students, and the promotion of good fellowship amongst its members, and hence it is that we have had the cordial co-operation of all those interested in the progress of architecture, no matter whether they be members of the Institute, of the Royal Academy, the Society of Architects, or of any other body. I trust that by a continuance of this policy we shall have an equally wide support in the future. There has been in the past one platform upon which all these men could meet, and that was the platform of education. It seems to have been tacitly admitted that, however divergent their views might be upon the burning questions of the day, they were all prepared to admit that some education was necessary for young men who wish to become architects, and that it is seldom, if ever, that all that is necessary can be obtained in the routine of an office. I appeal to all those, therefore, who are interested in the progress of architecture to sink their differences, and to give us their advice and co-operation in carrying on the work of this Association, irrespective of their belonging to any particular society or not. This is the basis of support upon which we have rested in the past, and upon which we shall also rely in the future. The education of architectural students in the past has been of a most haphazard and imperfect description. Here and there brilliant geniuses have stood forth in spite of the system, shining like beacon lights in the general gloom, and only serving by their brilliance to make the

surrounding darkness seem the blacker; but courses of instruction are not arranged to suit the genius. He is a *rara avis*, usually most erratic in his habits, and may be left to soar aloft on the bright wings of his imagination, untrammelled by the conventionalities of everyday requirements. We can leave him with confidence to pursue his own bright aerial flight. What we do want, however, is to effect a general raising of the standard of excellence among the earnest and thoughtful men, who will in after-life have to carry on much of the world's work. We do not profess to be able to create artists; for the artist, like the poet, is born, not made; but what we do profess to be able to do is to educate that artist when he has been created; to assist in developing the artistic instinct which may be within him, and to give him an opportunity of acquiring instruction, *pari passu* with his artistic development in those methods of practical construction and sanitation without which his artistic attainments are of very little value. Surely this is a basis upon which all architects may unite to assist us. That some such instruction is urgently required may be seen by anyone who will walk through the streets and examine the buildings which have been erected in the past fifty years or so. There are a few brilliant exceptions, but these form but a small percentage in the vast aggregate of dull, monotonous, common-place buildings, plastered over with meaningless ornament and covered with unnecessary features, which force themselves upon us on every side. We have heard much of late years about styles and the possibility of a new one being created, which is to become the style of the future; but what we want is "style," not "styles," and it is not until we cease masquerading in the fancy dress of every other country and period but our own that any real progress will be made towards the attainment of this object. What do we mean by "style"? "Style" in architecture is the language by which we express our thoughts, and it should be the natural expression of the requirements of a building controlled by the exigencies of climate and the proper use of the materials at our command. When we can be satisfied with giving a natural expression to the requirements and construction of our buildings, only using ornament where required for a definite purpose, and thinking less of past styles and more of modern requirements, then, and not till then, shall we once more have a style of our own. As long as we continue to reproduce the styles of the past in our work of to-day, and to palm them off upon a confiding public as our own creations, so long shall we delay the possibility of architecture once more becoming a living art amongst us. Let us study and reverence the work of the past, for there is much to be learned from it; but the highest and the best lesson of all is not to copy it. I would, in conclusion, urge you to think no trouble too great to achieve a satisfactory result in your work, and never to rest until you have made whatever is confided to your charge as perfect as possible for its purpose, and as beautiful as you can, no matter how small or simple the work may be. Everything is capable of being invested with some amount of individuality and interest if we will only take the trouble to think for ourselves, and not blindly follow the stereotyped forms laid down for us by others, and it is often the smallest things which require the most care and thought, and in which true artistic feeling is best displayed. Do not suppose that I would seek to curb or restrain the aspiring genius who dreams of doing great things; on the contrary, set your ideal as high as you possibly can, for it is given to few men to attain to the summit of their ambition, and the higher your aim the greater chance of your doing something; but it is not in cathedrals or other buildings of great size and importance alone that scope is afforded for originality and artistic feeling, but that everything which comes to your hand, no matter how small or insignificant, is capable of being made beautiful and suitable for its purpose, and such that it may give pleasure to those who have to use it. If you do this, you will have realised in the highest sense the meaning of our motto: "Design with beauty, build in truth."

Mr. ASTON WEBB, past-president, in proposing a vote of thanks to the President for his address, remarked that he had peculiar pleasure in doing so, as Mr. Cresswell was the first pupil he took. In that address the President had steered exactly between the two extreme views of architecture,

and all must rejoice in the excellent record of work done. In his own presidency the times were easy-going compared with to-day; they relied on mutual self-help, whereas now the Association rejoiced in a journal of its own, and even indulged in the luxury of a contested election. All felt their indebtedness to the originator of the new scheme, Mr. Stokes, and were glad to see that the first year's working had been carried out with so little loss. There was, he thought, a high diploma to be gained in the profession; but it was not one conferred by the association or any other body; it was to be obtained in the streets, in the appreciation of their buildings by their fellow-workers and the general public.

Mr. COLE A. ADAMS, past-president, seconded the motion, and in doing so congratulated the members, and especially Mr. Stokes, on the success of the new scheme, and proceeded to endorse the President's emphasis of the value to an architect of the measurement of old work. He concurred with the President that there was no temptation to cramming or mere superficial study in the Association's curriculum.

Professor ROBERT KERR, senior past-president, supported the motion, and remarked that the Association, founded nearly 50 years ago on the basis of mutual self-help, was now developing into an architectural university which was in no sense a cramming institution. After a year's experience of the new scheme he had a much higher opinion of it than at its inception. The work accomplished was thorough, solid, and substantial. There were two great colleges in London which were putting forth great efforts to help architectural education, but in one respect the Association had the advantage, in that all its lecturers and teachers were practical architects. He did not agree with the criticism that had been passed on the scheme that its management ought to have been placed in the hands of older men, for he believed they were the right men to carry it on. As for the great controversy that was being carried on just now as to whether architecture was a profession or an art, he held that they did not all want to be artists. He was not himself a great artist. At the recent dinner of the Association he happened to say this to a great church architect, one of the leading memorialists, who sat next him, adding that he drifted into the profession quite by accident, and to his surprise his neighbour answered, "So did I." So did a good many more; he believed Burges and Street did, and certainly Sir Gilbert Scott did. Many men became architects as a means of living, and for these the Association provided instruction. There were some geniuses who wished to soar into the empyrean. Let them fly, he said; it would do them good; and disperse their superfluous energy, while they would be glad enough presently to descend again to sober earth.

Mr. THOMAS BLASHILL, a past-president of thirty years ago, supported the motion, and suggested that an excursion to Italy should be arranged next spring. If one were decided upon he should be happy to undertake its management, as in the past.

The vote of thanks having been carried by acclamation, the President responded and said the committee would gladly accept Mr. Blashill's offer of help in organising another Italian excursion.

THEATRES.—XI.

By ERNEST A. E. WOODROW, A.R.I.B.A.

THE rules governing the widths of "every staircase, landing, lobby, corridor or passage," should also determine the dimensions that should be given to the doorways situated in such "staircase, landing, lobby, corridor, or passage." In chapter IX., published in the issue of the BUILDING NEWS of 30th September, I detailed the views of the various authorities upon the question of the width of exit: and it must be understood that the widths set forth in the regulations there quoted were to be measured at the narrowest part of the "staircase, landing, corridor, &c." As a rule, the narrowest part is the doorway, and, although the passage may be 4ft. 6in. in width, the doorway is often reduced to 4ft. or less, by the projection of the door-frame, the thickness of the door, when open, or the addition of the automatic bolt, as in Fig. 1. It is only necessary to suggest that the full width of the passage-way should be retained its entire length, that no reduction should occur at the door-

way, and various methods of overcoming the difficulty will occur to my readers.

Rule 25 of the London County Council, which I take as my text for this chapter, enacts that: "All doorways used by the public shall be at least 4ft. 6in. wide in the clear, with doors hung

Fig. 1.

in two folds made to open outwards towards the thoroughfare or way."

The 4ft. 6in. herein mentioned is, of course, "intended for the use of not more than 400 persons of the audience"; but if any portion of the house accommodates a larger number of the audience than 400 persons, the doorway must be increased in width by 6in. for every additional 100 persons until a maximum width of 9ft. be obtained.

All doors should, where the width is 4ft. 6in. or more, be "hung in two folds," so that pressure from within will force them to "open outwards" from the centre "towards the thoroughfare, or way." Where doors are used for entrance they, of course, must open inwards to admit the crowd, as well as outwards, to allow them to depart. When opened inwards the L.C.C. requires (as in the case of barriers) that they should lock back against

Fig. 2.

the wall in such a manner as to require a key to release them; and it is also well that they should fold back into a recess, in the same manner described as for barriers in the ninth chapter of this series. There is a difficulty often experienced in making external doors open outwards across the pavement: vestry authorities object, and the architect has to place his door in a recess, with the frame 2ft. 3in. back from the front wall, that is half the width of 4ft. 6in. as Fig. 2, so as not to allow the door to encroach upon the public footway. This unfortunately leaves a space, which too frequently becomes a public nuisance, and a sleeping place for vagrants; and to protect himself against such abuse of his premises the manager requires his architect to provide an external gate, or grille, to shut off this recess from public use or abuse at night. I must here remind my readers that the regulations we are now considering provide against movable or shifting gates, and insists that all doors used for entrances and all gates must be made to open both ways, &c. . . . again, no locks, monkey-tail, flush or barrel bolts, or locking bars, or other obstructions to exit, can be used on any doors, gates, or barriers. Gates, where they are necessary, should be made to open outwards in the same way as doors. I would suggest that they should be attached to the door by a bar, A, Fig. 3, which would permit them to open in conjunction with the door, by pressure from within. These gates could be so hung as to allow them being lifted off the hinges, and taken quite away, but if by any neglect on the part of an attendant, they were not removed they could be opened outwards in con-

nection with the doors, and be no obstruction to the general exit of the people. They should have no other fastening than what is required to secure the bar A to the door. (Fig. 3.)

Fig. 3.

Doors are frequently required in vestibules, passage-ways, and on staircases, to cut off the inrush of cold air to the auditorium: where such internal doors are required they should "be so hung as not to obstruct, when open, any gangway, passage, staircase, or landing."

"No door should open immediately upon a flight of steps, but a square landing at least the width of the doorway should be provided between such steps and such doorway." This is evidently to prevent any one opening a door, and finding themselves suddenly at the head of a long flight of stairs so that when there is a top landing outside the door two or three strides must be taken before reaching the first step, and the risk of precipitating headlong down the stairs avoided. It is often desirable where such internal doors are used, to glaze the upper panels, so that any one may see what is beyond the door, before opening it to rush through.

I now come to what is, perhaps, the most difficult part of my task in this chapter, the question of the fastenings upon doors. I feel I shall be compelled to mention by name the makers of fastenings which have been looked upon as suitable for the purpose of theatre doors; but in doing so I wish my readers to understand I in no way speak of these fastenings as superior the one to the other, or as better fitted for the purpose than others which may or may not have been mentioned by me; neither do I admit that I consider them perfect, or imperfect, in detail or construction. I speak only of the principle of their action in the broadest sense.

The rule which has caused the invention of automatic bolts, is a further part of the L.C.C. twenty-fifth regulation.

"All exit doors having fastenings shall be fastened by automatic bolts only, of a pattern to be approved by the Council; but where such doors are also to be used by the public for entrances, they shall be fastened with espagnolette or lever bolts only, of a pattern to be approved in each case by the Council, and fitted with lever handles at a height of 3ft. 6in. from the floor."

"All barriers and internal doors shall be made to open outwards, with no other fastenings than automatic bolts."

"No locks, monkey-tail, flush or barrel bolts, or locking bars, or other obstructions to exit, shall be used on any doors, gates, or barriers."

The difficulty that the manufacturer has to overcome (I do not say whether or not the bolts in the market have surmounted this difficulty) is to provide a fastening that will at once give way to the slightest pressure from within, and yet, at the same time be a security against the outside world, so as to protect the property of the theatre. One manufacturer writes me that: "The history of panic bolts, which has been one of continual development, is based upon the initial requirements of the L.C.C. and the necessities and peculiarities of customers and users. We have found a successful apparatus must combine ease in opening by a panic-stricken public inside the building; economy in first cost; durability and strength in all the parts; simplicity in construction; freedom from difficulties in fixing; applicability to single and folding doors, hung in rebated frames opening outwards only, and single and folding doors to swing, to doors of any material, with square or carved heads. There must be means for opening from the outside when necessary. The

least possible encroachment upon width of opening when the doors are opened, has also had to be taken into consideration, as well as a secure fastening of the doors so that no unauthorised person can obtain admission."

This clearly puts forth the work required by an automatic bolt, and are the views and opinions of Mr. Copping on the subject. An automatic bolt should not lessen the width of the doorway by its projection, nor should it be of such a pattern as to prevent any one—intentionally or inadvertently—rendering the unfastening of the doors impossible, by placing an umbrella or walking-stick, for example, between the operating horizontal arm and the door.

Fig. 4 is a sketch of Kaye's well-known automatic bolt; while pressure against the

Fig. 4.

bar A releases the fastenings. In "Baker's" bolt, instead of an iron or brass bar, there is a slight wooden projection across the central rail. It is claimed, that by this apparatus doors can be securely fastened, so that they cannot be opened from the outside, but that they will be liberated and free to open immediately any pressure is applied from the inside, either directly or indirectly to the fastening. There are other patents differing, doubtless, in the internal mechanism, the names of the makers I am unable to give, on account of having insufficient information on the subject, although I have endeavoured to collect it, in preparation for this chapter. One desideratum in automatic fastenings is, that when the bolt or fastening is once drawn, it should be held back so as not to catch in the floor or door frame, and cause the door to get fast. The fearful disaster at Sunderland, it will be remembered, was caused by a barrel bolt catching in the floor of the landing. This was a lesson taught with such dreadful severity, that one shudders at the sight of inappropriate fastenings on any doors in a building (licensed or unlicensed) where vast congregations of people meet. Much, indeed, which I have had to say in these papers has been said by me with a view of its application to other buildings than theatres, for the public need as great a protection in the church, lecture-hall, or exhibition as in any theatre or music-hall. The improvements which are likely to arise in the future development of automatic bolts are such as to permit one to expect them to be of a pattern which will be easily adapted to entrance doors opening both ways, thus doing away with the necessity of lever-handle bolts; in fact, I believe that the various makers have already placed before the public modifications of their automatic bolts applicable to these requirements.

Following the course I have adopted in former chapters, I must now briefly review the opinions of others, on the part of the subject now under our consideration, in order that we may learn what to adopt, avoid, modify, or convert to the usages of a theatre. In Italy there is a rule that attendants must be provided (at the expense of the management) one at every exit, or for more than one exit if in the same line, and within a short distance of each other. Such attendant must be provided with a key, and be in readiness to open the doors in case of emergency. Personally, I think it more than likely than in "case of emergency" the said attendant would think of himself before the public, and it appears to me to be a very unwise rule, for it places the safety of the public in the hands of one man. As the Italian regulations are mostly so very stringent, I wonder at the conditions in this particular one. Keys are so apt to be lost when most wanted, and even the provision made in the Brussels regulation does not, to me, meet the exigencies of the case. Here the external doors, only, may have locks, which must always open with one pass

key, and every emergency door must have a key placed in a glazed box within reach of the public. From this any one who was desirous of creating mischief could take the key away, and leave the door locked.

The go-ahead Americans in New York have not yet demanded automatic panic bolts, for here movable bolts are allowed, which must be kept drawn during the performance. But suppose the man whose duty it is to draw the bolt does not do it? Berlin asks for all doors to be unlocked during the performance. (Should not they be all unlocked before the audience is admitted?) Hamburg requires that the fastenings on the side next the audience shall be of such a pattern as to be easily and quickly opened by the public. The act of opening must not necessitate stooping down, the knob must not be above the shoulder, and the fastening must be as simple as possible. This restriction as to height is a good one, as the pressure against the door is from elbow to shoulder height.

The St. Petersburg rule, like that of Hamburg, accords more with that of London than any others I have quoted. "All doors and windows, (which must be casement hung), must be supplied with easy working apparatus for opening them, with handles not lower than 2ft. 6in. from the floor. Bolts are not permitted under any circumstances."

With regard to locks on other than entrance and exit doors, i.e., on dressing-rooms, offices, stores, saloon doors, &c., these should be all made to pass a master key, and each fireman, the manager, or other responsible persons should be provided with such a key, so as to be able to enter and examine any room at any time. No room should be so private in a theatre that the fireman cannot obtain admission at any time. Fires frequently occur in rooms that have not been entered for an hour or more; a smouldering fire may start in a locked-up dressing-room or office of a theatre; therefore the fireman should be able to examine all parts at all times. The other separate keys of each individual room should be hung on a "key-board" in the stage-door keeper's or porter's office. Here they can be quickly obtained, and when it is known that they are always to be found in one place when the room is locked, there is great saving of time in searching for the attendant, who may or may not be expected to have possession of it.

My attention has been drawn to a working model of a patent exit-door invented by Messrs. Lancaster and Nixon, a short description of which the character of these articles demands. The following account of the working of the invention has been furnished me by the patentees.

The door is divided vertically, so as to form two doors, one portion slightly overlapping the other on the outer side, the portion that overlaps being held at the foot by a spring operating on a catch. Attached to the top of each door is a spring forcing them both open the moment the catch at the foot is withdrawn. This withdrawal is simply brought about by the pressure of the foot, as a person approaches the door from within. The floor in the vicinity of the door, on the inner side is a small platform, so constructed that a weight of 40lb. or more, pressing upon it, will produce a depression along a transverse line to the extent of an inch, thereby forcing down the spring to which the catch is attached that holds the doors. The catch only requires a drop of a quarter of an inch in order to withdraw it, whereupon the doors at once fly open, and so remain until restored by hand to the closed position. The catch is a small vertical bolt, which sinks below the level of the platform as long as the latter is acted upon by the specified weight. Thus a crowd rushing out from the building would meet with no obstruction, and the slight depression in the centre of the platform would create so gentle a slope as to cause no embarrassment. With the exception of this little bolt or stud, there is no fastening of any kind attached to the doors. A person seeking to escape has simply to run within a step or two of the threshold, and the doors fly open, presenting a perfectly unimpeded means of exit. The action is so entirely automatic that no trepidation or blundering on the part of the individual seeking to escape will have any tendency to prevent the opening of the doors. On the other hand, until the doors are thus automatically opened from the inside there is no possibility of any one entering from without. The only fear that at present occurs to my mind is that should any dust or obstruction collect beneath the platform (while

is made to "produce a depression along a transverse line to the extent of an inch") the automatic action would not be produced, and the doors remain unopened. Where, however, the doors were in constant use this fear would be overcome, as any obstruction would be easily removed. On the question of cost I am not informed sufficiently to speak here.

I have lately had some correspondence with two French gentlemen, who have forwarded me the following description of a method advocated by them as a means of reducing the calamities from panic. "M. René Résuche, aided by his colleague, M. A. Vailly, has been led by his studies and inquiries," says the *Figaro*, "to the discovery of a 'system of instantaneous evacuation,' by means of which thousands of spectators in any theatre can be restored to the open air in the space of a few seconds. His invention can be modified so as to adapt itself to theatres standing alone, or built upon two or three sides. There is only one indispensable condition, that on every disengaged side, and on each story, there should be outside balconies connected by staircases with those below." . . . "Résuche's invention deals especially with the walls of the buildings. These movable walls must be made of two sheets of iron, the space between them being filled up with refuse of cork or some such light material, which will retain the heat, without injuring the acoustic properties. This ingenious wall is suspended on chains fitted with pulleys and balance-weights connected with a windlass placed in the basement. In case of fire the windlass is put out of gear, the iron wall descends by its own weight into the space which has been provided for it in the ground, like the well of a lift, and all the balconies on every side of the theatre are instantly free. In the second system of instantaneous evacuation, the walls of each story are mounted on hinges, and connected outside by cables running over pulleys inside with balance-weights for the stoppage. One ungearing is enough, the walls descend like a draw-bridge, and resting on the balustrades already in position, form so many balconies. In a third system, according to the site of the building, the wall runs horizontally in grooves fitted with rollers and balance-weights, and it then sets free an opening corresponding with its own width. But in every case, whether the theatre be detached or surrounded by other buildings, the same method—namely, that of movable iron walls—must be applied."

Such is the description of what may briefly be termed automatic doors opening onto external balconies and external staircases; but there is one serious drawback, that I can point out without having seen the invention applied—the cause of effecting the working of the apparatus is fire. In case of fire the windlass is put out of gear, &c. How many fatal crushes and panics have occurred without one spark of fire? Sunderland, Hampstead occur in our minds at once. The principle of doors onto outside balconies is a good one, but to employ the enemy to make the means efficient is radically wrong. How are such "safety valves" to act when panic arises without fire? How in such a case as that at Bolton this week, when, during a fire in the town the wife of a fireman ran to the theatre, where her husband was witnessing a performance, and shouted to him that there was a fire? The audience misunderstood her, and rose en masse. Several ladies fainted. The manager rushed to the stage and explained the circumstances, but a quarter of an hour elapsed before order was restored. Simple cases like these have to be met, as well as great disasters like the Ring Theatre.

DRAINAGE AND PLUMBING SPECIFICATION.

By ARTHUR BAKER, F.R.I.B.A.

PREFACE.

MUCH valuable information and instruction in the details of plumbing and sanitary work has been given in the works of T. Pridgin, Teale, Rogers Field, S. Stevens Hellyer, J. Wright Clarke, William R. Maguire, &c., with which all students should be familiar before they attempt drainage work. Yet, with all this knowledge at hand the attempts at modern drainage are but too frequently failures. The experience of the author has led him to believe that this arises as much, if not more, from either a want of knowledge or of attention to these details, than

of the general principles of sanitation. This has led to their being left to the discretion of the plumber, whose knowledge rarely extends beyond the mechanical details of the trade. Those also who are conversant with the subject may be guilty of imperfect specification writing, through the labour required in remembering and arranging a mass of technical details. To both these classes, therefore, the author hopes he may be useful in his effort to combine in the following specification both his personal experience and the views of the best sanitary authorities. For the sake of brevity, the usual conditions of the contract, which would include insurance, the provision of water, maintenance of works for a certain period after they are completed, &c., &c., are omitted. In writing the condition for payment, the architect should be careful to provide that the first certificate for payment should not be given until the drains have been tested the second time (see Clause 14). It is better, however, if possible, to postpone payment till the whole of the work is completed. A drawback should be kept for a period in proportion to the extent of the work, and sufficient to cover the probable cost of making good defects which may arise after the completion. It should be noticed that frequent reference is made to the "Plans," which should be drawn with the greatest care, with details given of the inspection chambers and all junctions of the pipes with the drain, &c., the levels and falls of pipes being figured. As no specification could be made to meet all circumstances, alternative clauses have been given suggesting modes of treatment applicable to varying cases. The author has left to the judgment of his readers the question of the selection of fittings, which must depend upon the money at command and on local circumstances. He would only strongly impress the necessity of the greatest care in selection, personal tests being preferred to faith in advertisements.

GENERAL CLAUSES AND MATERIALS.

1. Portland cement :—

The Portland cement to be sound, fine, slow-setting, air-slaked, strong cement, capable of bearing the following tests* :—

1st. *For Soundness*.—Make on three pieces of glass three pats of cement, 2in. diameter, $\frac{1}{2}$ in. thick in the centre, and thin at the edge; one of neat cement, placed 24 hours after it is gauged in cold water for seven days, must be perfectly free from cracks, and the edges must not leave the glass; one as above, in the proportion of 1 of cement to 3 of sand; the other, of neat cement, kept in the air, must be, when set, of a greyish-white colour, and must be free from cracks and from any buff stains.

2nd. *For Fineness*.—The cement must be able to pass through a sieve of 5,625 meshes to the square inch, leaving a residue of not more than 10 per cent.

3rd. *For Slow Setting*.—A pat of neat cement must be capable of indentation of the thumb-nail two hours after it is made.

4th. *For Strength*.—One cubic inch of neat cement, mixed with the minimum quantity of water necessary to set the cement when gauged into a mould, and (24 hours after it has been gauged) immersed in water 7 days, must be capable of bearing a tensile strain of 350lb., and 480lb. after 28 days.

5th. *Specific Gravity*.—To be not less than 3.1 after drying for 15 minutes in a desiccator at 212° Fahr., and this shall be ascertained by a Schumann or other approved apparatus.

OR, the contractor may supply a guarantee from the manufacturer that the cement supplied for the purpose of the work herein specified is capable of bearing the above tests, and the architect, at his option, may accept the same, but without prejudice to the liability of the contractor under Clause — in the general conditions of the contract referring to maintenance of works.

2. Delivery of cement :—

The cement required for the work, or such portions of it as may be directed by the architect, is to be deposited on the works — days after the contract is signed.

3. Sand :—

The sand to be quartz sand of approved quality, free from salt, vegetable, iron, clay, or slimy or

* The quality of this cement would be rather above that usually to be obtained, but the best manufacturers would supply it at a slightly increased cost, and guarantee its capability of standing the above tests.

earthy matter, the whole to pass through a sieve of 400 meshes per square inch, and the whole to be retained on a sieve of 900 meshes per square inch.

4. Concrete :—

The concrete is to be composed of well-washed Thames ballast, clean gravel, or broken brick of a size to pass through a $\frac{1}{2}$ in. mesh, and approved by the architect, with sufficient sand to fill up the interstices in the proportion of five parts of the above mixture of gravel and sand to one part of Portland cement, to be well mixed and incorporated with the full quantity of water which the material will absorb.

5. Grout for filling round sockets of pipes :—

The grout for filling under sockets of pipes to be made of three parts of sand to one part of cement.

6. Cement mortar :—

The cement mortar for building and rendering walls and grouting to be composed of three parts of clean, sharp sand, and one part of Portland cement.

7. Cement for making pipe-joints :—

The cement for making pipe-joints and floating the sides of inspection chambers to be composed of one part of clean, sharp sand, and five parts of Portland cement, the cement to be mixed fresh for each joint. (See also clause 22.)

8. Cement to be used in contact with lead or iron pipes :—

All concrete to be made, and brickwork to be set with, Portland cement, no lime being allowed to come in contact with the lead or iron pipes.

9. Pipes to be tarred :—

All lead pipes buried in, or passing through, walls to be tarred before they are fixed.

10. Cutting away and making good floors :—

Do all necessary cutting away of wood, tile, stone, or other floors, and make holes through walls for pipes, and make good to ditto, and to pointing and surfaces of walls, and leave all perfect at completion.

11. Remove from premises all waste water, &c., arising from the works* :—

Keep all w.c.'s and all sinks, lavatories, baths, gullies, and house and yard drains free from all waste water, slops, dirt, &c., arising from the works, and remove all such waste water, slops, dirt, &c., from the premises. A penalty of £ will be enforced for every occasion on which w.c.'s, sinks, baths, lavatories, gullies, drains, &c., are used contrary to this clause.

12. Protect w.c. and other fittings :—

Protect all w.c., sink, bath, and other fittings, and all pipes, and put temporary wood casings to all terminals of pipes liable to be injured, or to have dust or rubbish dropped into them during the progress of the work, and leave clean and in perfect working order at completion.

13. Examine fittings :—

All fittings before they are fixed to be carefully examined by the contractor, who will be responsible for their perfect condition.

14. Testing :—

The drain-pipes, including the pipes between the siphon and the sewer, are to be hydraulically tested for at least eight hours†—first, after the joints are made, and before the pipes are covered up, and a second time at a period of . . . days† after they are covered up; the soil-pipes are to be hydraulically tested before the apparatuses are fixed, and the whole of the drainage system, including all siphons, gullies, inspection chambers, &c., and w.c.'s, sinks, lavatories, bath, and other fittings, to be again subject to such hydraulic, peppermint, smoke, and other tests, as the architect may require upon the completion of the work before it is handed over to the employer. The contractor is to supply all necessary air-tight stoppers, manhole cover keys, peppermint, and

* This clause should also be inserted in specification for painting, decoration, &c. £2 is an effective fine.

† This is necessary, that the water may have time to soak into joint made with imperfectly-mixed cement, or with cement containing unslaked particles, and to enable the fracture of the socket caused by the expansion to be discerned. The author has known of cases of pipe-sockets being fractured, through the use of bad cement, after the pipes had been successfully tested on two occasions.

† Say, 28 days.

other appliances and materials and labour required for testing.

15. Regulations of water co.'s, &c.*:—

The regulations of the Water Co. and of the public authorities are to be observed, and the cost of laying on the water is to be paid by the contractor. If the water co.'s regulations are found to be at variance with any clauses in the specification, notice is to be given immediately to the architect.

EXCAVATING.

16. Digging trenches:—

Excavate for trenches and foundations of inspection chambers, branches, gullies, &c., to the depth shown on the drawings, or as may be required for the pipes, drains, gullies, inspection chambers, &c. Do all necessary planking, strutting, and shoring, and keep trenches free from water, fill in ground after the pipes are laid, and ram ditto, and make good surfaces.

17. Removing soft and impregnated earth:—

Remove all soft earth, and earth impregnated with sewage matter, and fill up with clean gravel or hard dry brick rubbish, and well ram ditto, provided, however, that the excavation does not exceed the depth of 12in. below the underside of the drain-pipes when laid, in which case the space is to be filled with concrete.

18. Width of trenches†:—

The trenches to be not less than . . . wide for 6in. pipes, and . . . wide for 4in. pipes, and the ground to be made up to the required levels, and well rammed, the depth of the trenches, &c., to be not less than 6in. below the under side of the pipe when laid.

19. Cutting through walls:—

Do all necessary cutting through walls, and shoring and underpinning ditto where pipes pass under or through walls, and make good ditto with cement.

20. Making good surfaces:—

Make good the surface of all roads, paths, pavements, &c., and all wood and stone floors, and wood and stone steps disturbed in laying drains or fixing apparatus which are not otherwise specified to be altered or removed.

INSPECTION CHAMBERS.

21. Floor and walls of chamber:—

Form inspection chambers of the sizes shown upon the drawings with, concrete floor, and foundations to walls . . . thick, and walls of brickwork in cement . . . thick, the inside measurement of the chamber to be . . .

OR. form floor and walls of inspection chambers with concrete . . . thick, the inside measurement of the chamber to be . . .

22. Side inlets:—

Provide and fix in all inspection chambers . . . channel pipes, with . . . side inlet channels as shown on drawings. Fill in between the channels with concrete flush with the face of channel, and slope ditto to sides of chamber, and render, with cement (Clause 6), and float with

23. Channels:—

The channels in inspection chambers to be laid in the direction of the outlet of the main drain, and to be of suitable curves, the socket end being set square with the branch pipe, and the outlet lineable with the side of the channel (see Fig. 1). The curves of channels must not be as shown at C (see Fig. 1).

24. Rendering to sides of chamber:—

The sides of inspection chambers to be rendered with Portland cement (see Clause 6), and floated with cement (Clause 7), and finished to a perfectly smooth surface with neat cement.

25. Iron steps:—

Provide No. . . . ½in. wrought-iron steps, with returns flattened and turned up at the ends, and build ditto into the walls of inspection chamber, and paint ditto four coats.

26. Inspection chamber covers*:—

Provide iron frames and covers for inspection chambers, and well bed down do., and fix level with pavement, and provide and fill the channels in ditto with . . .

STONEWARE PIPES.

27. Stoneware pipes:—

Earthenware drain-pipes to be, or other approved socketed stoneware tested pipes, completely salt glazed and vitrified throughout, of true bore and form, of even thickness, and of the sizes shown upon the plans, the thickness of pipes to be not less than ½in. for 4in. and 6in. pipes, ¾in. for 9in. pipes, and 1½in. for 12in. pipes.

28. Pipe-laying†:—

The pipes to be laid to falls, with a bevelled straight-edge, and a gauge the length from socket to socket of the pipe when fixed, to insure the spigot being driven home into the socket, as

FIG. 2.

shown on drawings, on a bed of Portland-cement concrete, 6in. thick and 18in. wide for 4in. pipes, and 20in. wide for 6in. pipes, with additional thickness when required to make good clay hole, or when soft earth has been removed (see Clause 17), and leave space under each socket for making the joint; and after the joint is made and tested (see Clause 14), they shall be covered with concrete 6in. thick, the space round the joint being run with grout (see Clause 5). The concrete bed must be carefully cleaned before the pipes are covered with concrete, care being taken that the concrete covering is well filled and rammed in under the pipes.

OR. lay bottom of trenches with a layer of concrete, 3in. thick and 18in. wide for 4in. pipes, and 20in. wide for 6in. pipes, with additional thickness when required to make good clay hole, or when soft earth has been removed (see Clause 17), and lay pipes with a bevelled straight-edge and a gauge the length from socket to socket of the pipe when fixed, to insure the spigot being driven home into the socket, to falls as shown on drawings, on brick or concrete piers 3in. high, set in cement, and joint and test pipes, clean concrete bed; fill in under the pipes with concrete 3in. thick, and over and round pipes with concrete 6in. thick.

OR. the pipes to be laid to falls, with a bevelled straight-edge and a gauge the length from socket to socket of the pipe when fixed, to insure the spigot being driven home into the socket, as shown on drawings, on 9in. piers of concrete 6in. thick,

and after the joints have been made and tested, the pipes are to be filled in under and over with concrete 6in. thick, so that the concreting round the pipe may be one solid continuous mass (see Fig. 2). Put such extra thickness under piers and pipes as may be required to make good clay holes, or where soft earth has been removed.

29. Extra fall to channels and curved pipes:—

Give an extra fall of lin. in each length to all curved and channel-pipes, and as much fall above lin. as circumstances will allow to the pipe next outlet of grease-trap.

The pipe-joints to be made in the following manner:—A strand of yarn steeped in cement grout to be wound round the spigot end to prevent the cement entering the pipe; the yarn to be driven well up the socket,* and the space between the pipe and the socket to be completely filled with Portland cement (see Fig. 3);

FIG. 3.

the surface round the socket to be worked to a smooth face; the inside of each pipe to be cleaned with a hoe and a mop after the joint is made.

31. Opercular pipe:—

Fix an opercular pipe as near the eye of sewer as possible and bed down ditto with cement, and make good over ditto after the drain is tested.†

32. Arches over drains:—

Form rough arches in walls over all drains, and leave clear space between arch and pipe; or fill ditto with earth or other compressible material.

33. Diminishing pipes‡:—

All connections of drain-pipes, and also of drain-pipes with sockets of gullies of varying sizes, to be made with proper diminishing-pipes.

34. Bends:—

All changes in the direction of pipes to be formed with proper curved bends.

35. Channel bends:—

All pipe-bends and channel bends to be of such a curve that the socket and spigot ends may fit the inlet and outlet pipe (see A¹, Fig. 1, if a straight pipe is used, or A² if a curved pipe is used). Pipes are on no account to be fitted to channel bends in the manner shown at B on Fig. 1.

36. Back flow in branch drains:—

Single junctions to be, if possible, fixed as in Fig. 4, and not as Fig. 5, to avoid back-flow into branch drains.

37. Screw-plugs:—

Inspection eyes to be fitted with expanding screw stoppers.

38. Bedding-down drain stoppers:—

Well bed down with lime and hair mortar all stoneware or metal stoppers to drains.

CAST-IRON PIPES.

39. Weights of pipes above ground:—

All cast-iron soil and water-pipes fixed above ground to be of the following weights:

Diameter. in.	Length. ft. in.	Weight. lb.
3	6 0	45
4	6 0	60
4½	6 0	70
5	6 0	82

* Some prefer to omit the yarn steeped in cement. There are various other joints, such as Doulton's improved Stamford joint, which are much used.

† Care should be taken to note and describe the treatment necessary in making the connection between the house drain and the sewer, which may vary greatly in different houses; and if the sewer is of brick, the outside of the sewer next the house may require rendering or pointing to prevent leakage.

‡ There are two kinds of diminishing pipes: one tapers in every direction, the other tapers only on the upper side

cement (Clause 7), and finished to perfectly smooth surface with neat cement.

* The architect is advised to ascertain these regulations before writing the specification, and to inquire if they are strictly enforced.

† The width of trenches may depend on the nature of the soil. In gravel or stiff clay they might be only sufficiently wide to receive the concrete—viz., 18in. for 4in. pipes, and 20in. for 6in. pipes.

* Describe here mode of fixing required for the pattern selected.

† If the soil is clay, clause C would be the best, for if A or B is used, the top of the concrete bed may become dirty, and if not perfectly cleaned the dirt would prevent the two layers of concrete from uniting.

49. Weights of pipes underground :—

All cast-iron soil and water-pipes fixed underground to be of the following weights :

Diameter. in.	Length. ft. in.	Weight. cwt. qr. lb.	Thickness. in.
3	9 4	1 0 14	...
4	9 4	1 2 0	...
5	9 4	2 0 0	1 6
6	9 4	2 2 0	1 6
7	9 4	3 0 0	...
9	9 4	4 0 14	...
12	9 4	6 2 13	...

1. Weights of rain-water pipes :—

Rain-water pipes to be of not less than the following weights :

Size. in.	Length. ft. in.	Weight. lb.
2 1/2 by 2	6 0	16
3 1/2 by 2 1/2	6 0	21
4 1/2 by 3	6 0	28

Round.

Size. in.	Length. ft. in.	Ordinary. lb.	Heavy. lb.
2 1/2	6 0	18	*
3	6 0	22	32
3 1/2	6 0	26	40
4	6 0	31	50
5	6 0	44	70

42. Pipes to be sound :—

All cast-iron soil and water-pipes to be sound and free from pin-holes and cracks, and of an equal thickness throughout. The underground pipes shall be capable of standing a pressure of 400ft. head of water, and all pipes which are burst or cracked in making the joints are to be taken out and broken up. The socket must be sufficiently large to allow of caulking the joint.

48. Rainwater pipes to be sound :—

All cast-iron rain-water pipes to be sound and free from cracks, and of an equal thickness

throughout, and all pipes which are burst or cracked in making the joint are to be taken out and broken up.

44. Joints to cast-iron soil and water-pipes :—

Joints to be made with tarred spun-yarn of an equal thickness all round the pipe, and driven into socket (care being taken that it does not enter the pipe), and caulked with molten soft pig lead to a depth of not less than from 2in. to 2 1/2 in.

45. Joints to rain-water pipes :—

Paint the spigot end and socket of rain-water pipes, and make joint with red and white lead, putty and paint ditto. two coats in addition to the painting specified for iron work generally.

46. Angus Smith's solution :—

All cast-iron soil and water-pipes to be coated with Angus Smith's solution inside and out.

47. Laying pipes underground :—

Underground iron pipes to be laid on a bed of concrete 6in. thick and 5in. wider on each side than the external diameter of the pipe, with additional thickness when required to make good clay holes, or where soft earth has been removed.

48. Fixing pipes above ground :—

Pipes fixed above ground to be secured to the

sides of the wall with iron bracket hooks of sufficient strength to carry four times the weight of the pipe fixed into the wall (see Fig. 6).

49. Rain-water pipes fixed clear of walls :—

Rain-water pipe heads, shoes, &c., to be fixed

FIG. 6.

with ears projecting beyond the face of the wall, as shown at on the drawing.

OR. the rain-water pipes, &c., unless otherwise specified, to be fixed with all necessary heads, shoes, &c., of the following patterns,

OR. of the following P.C. values.

TRAPS, GULLIES, &c.

50. Sewer intercepting traps :—

Provide and fix in inspection chamber a sewer intercepting siphon-trap, and connect ditto with sewer with all necessary 6in. pipes.

51. Cascade action in intercepting traps* :—

All sewer and drain intercepting traps to have a drop of inches from the inlet to the standing water in the trap.

52. Gully at foot of rain-water pipe :—

Provide and fix at foot of rain-water pipe a gully with iron grating, and with an obtuse arm to receive rain-water pipe, and connect ditto with drain, and fit pipe with obtuse bend, and connect with arm of gully.

OR. provide and fix at foot of rain-water pipe a gully with iron grating, and connect ditto with drain, and fit shoe to rain-water pipe to discharge over gully.

OR. put shoe at foot of rain-water pipe, and provide and fix under ditto a Doulton's or other approved gully-channel, and a gully, with iron grating, and connect ditto to drain.

53. Traps fixed level :—

All trapped gullies to be fixed perfectly level, so as to maintain their proper seal.

54. Gullies bedded in concrete :—

All stoneware, gullies, traps, &c., unless otherwise specified, to be bedded and cased in concrete.

55. Traps and basins of w.c.'s bedded in concrete :—

The earthenware traps and basins of w.c.'s to be well bedded and cased in concrete 6in. thick to a height of 3in. above the top of the outgo of the trap, and well grout round basin and trap.

56. Gullies fixed below level of yards :—

The gratings of gullies in yards and areas when fixed against walls to be, if possible, not

less than 2in. below the floor of yard or area, and the floor to be dished out (see Fig. 7), and gratings of gullies fixed at a distance from walls to be fixed 1in. below floor of yard or area, and the floor to be sloped to ditto with a regular fall.

OR. fix over gully below the floor a

* This clause would not be necessary if the pattern to be used is specified.

. or other approved stoneware dished cover (see Fig. 8).

57. Seal of lead and earthenware traps to "wash down" w.c.'s :—

The lead and earthenware traps to "wash down" closets to have a seal of not less than 1 1/2 in., and to be of such a form that the water may stand at least 3/4 in. in an earthenware trap,

FIG. 9.

and 1 1/2 in. in a lead trap above the junction of basin and trap (see Fig. 9).

58. Inlets of traps :—

The inlets in the sides of traps for vertical pipes to be oblique right-angle inlets, to be used only for horizontal pipes.

59. Diameter of wastes and their traps :—

All lead waste-pipes and traps connected to them to be of the same diameter.

60. Waste-pipes to fit inlet of traps :—

All lead waste-pipes of a smaller diameter than the inlet of traps to which they are connected to be tapered out and flanged to fit the inlet of trap.

61. Enlarged mouth to traps :—

Traps to sinks and lavatories to have their mouths enlarged to the same diameter as the washer of sink.

62. Traps fixed directly under fittings :—

All traps, unless otherwise specified, to be fixed directly under the fittings, without any length of vertical pipe between the trap and the fittings.

63. Weeping pipe :—

To traps which are seldom charged with water, as at see plan, provide and fix from the nearest supply-pipe or waste-pipe to a 1/2 in. lead weeping pipe.

64. Running traps :—

No traps (running traps) are to be fixed in horizontal pipes.

CHIPS.

A new Wesleyan chapel at Stourton, near Leeds, was opened on Saturday. It is Italian Renaissance in style, and is built of brick. Sittings for 600 persons have been provided in area and end gallery at a cost of £2,000. Mr. Thomas Howdill, Oxford-row, Leeds, is the architect.

The memorial-stone of the Episcopalian Church of St. Saviour's, in Port Dundas-road, Glasgow, was laid on Saturday. Built of red sandstone, the edifice will, when completed, consist of nave, chancel, and vestry, and in addition there will be a hall for mission work. The nave, which is the only section of the building which will be proceeded with at once, will seat 350 people.

The memorial stone of a Congregational school chapel was laid at Staple Hill, Bristol, on the 19th inst. The estimated cost of the scheme in its entirety is £4,000, but it is proposed for the present to erect school premises only, consisting of a hall, seating 300 persons, a room for infants, and six class-rooms. The large hall will, for a time, serve the combined use of chapel and Sunday school. The estimated cost of this section of the scheme is £1,600. The school will be of simple Gothic design, built of Pennant stone, with freestone dressings, and the hall is to be floored with wooden blocks. Mr. Frank Scutt, of Bishopston, is the builder.

In order to safeguard their 11th-century cathedral from fire, the inhabitants of Drontheim purpose that the roof should be replaced by one of iron covered with copper, and have actually asked the Storting to make a grant of 100,000 kroner, or £55,000 sterling. Since 1818, the Kings of Norway have been crowned in the cathedral of Drontheim.

* These are sometimes used for soil-pipes with a caulked tow and red lead joint, but this cannot be recommended for good work.

WHITECHAPEL FREE PUBLIC LIBRARY AND MUSEUM.

THIS building, which was formally opened by Lord Rosebery on Tuesday last, is erected upon a site 131ft. long and 46ft. wide, facing High-street, Whitechapel. The planning was a difficult matter, owing to there being no rights of light on the west side or in the rear, whilst some ancient lights on the east side had to be avoided. The entrance is in the centre of the front, and has on the left hand the lending library, and on the right a room for ladies and a room for boys. In the rear is the large reading-room, 45ft. wide and 69ft. long, fitted with newspaper stands and tables. Light is obtained by ceiling lights at the far end and by large windows looking into the area formed to avoid the ancient lights. A wide staircase gives access to the reference library, running the whole width of the front, and 36ft. wide. It is fitted with counter, bookcases, and lift for books. A circular staircase communicates with lending library and store in basement. Beyond the staircase is the commissioner's room and museum, the latter 45ft. long and 30ft. wide, lit by a ceiling light, and fitted with cases for the display of a collection of natural history presented by the Rev. D. Greatorex. A private staircase gives access to the librarian's residence on the second floor, facing the front. In the basement is a book-store, cellars, bookbinder's room, and caretaker's apartments. The front is faced with red Stanstead bricks and buff terracotta dressings from the Burman-totts works. A richly-modelled band runs across the whole width. The central turret contains a ventilator connected by a trunk from basement, lending and reference library. The works have been carefully carried out by Mr. W. Gladding, of Byfield Works, Mile End, the contract being £6,454, given by Mr. J. Passmore Edwards, the proprietor of the BUILDING NEWS, the *Echo*, the *Weekly Times* and *Echo*, and other journals. The museum fittings are by Mr. S. Elliott, of Newbury. The plans were selected in a limited competition, and were prepared by Messrs. Potts, Son, and Hennings, of 1, Finsbury's Inn and Victoria Buildings, Manchester, under whose supervision the whole of the works have been carried out. In the course of his able opening address on Tuesday, in which Lord Rosebery dealt at some length with the question of the diffusion of cheap literature and the revival of municipal unity, he said: I do not know again whether it is the cause of municipal life or the effect of municipal life, but we owe a great deal to the benefactors of

London—to men like Mr. Passmore Edwards. Now you have heard from your chairman how it was that, having collected a certain sum of money and being at the last gasp, you sent an emissary to Mr. Edwards, knowing his large public spirit, and instead of giving the sum you wanted, he gave the whole cost of the affair. (A voice: And 1,000 volumes of books besides.) He has given so many thousand books in London that I did not think it necessary to mention it on this occasion. But on this occasion, if I may say so, he raised and dignified his gift by the manner in which he gave it. There were no pompous paragraphs, no florid articles, no blowing of trumpets and beating of drums. He sent a note and a cheque, and the note had in it so remarkable a sentence that I ask the permission of the writer to quote it to this meeting. It said: "I cheerfully comply with your request, and I do this, not merely from a sense of duty, but because I think it a distinct privilege to assist in lightening and brightening the lot of our East-end fellow-citizens." And in another note he said: "I have long ago thought the East-end of London has stupendous, uncanceled claims on the wealthy and well-to-do people of the West-end, and it affords me unalloyed gratification that I have been able to wipe out some portion of our moral indebtedness." Well, acts and language like this find an echo in all our hearts. And you know that this is by no means the only act that Mr. Passmore Edwards has done of this kind. He has been in Bethnal-green, he has been to the Borough-road Polytechnic that I opened the other day—I don't know if he ventured to smoke on that occasion—(laughter)—he is strongly under suspicion of having been to Battersea to see the Albert Palace—in fact, wherever he goes the suspicion of benevolence dogs his footsteps.

NEW PREMISES, 287, STRAND.

THE material of this building is red brick and buff terracotta. Messrs. George Trollope and Sons are the builders, and Mr. William Young, of 6, Lancaster-place, is the architect.

CHRIST CHURCH NEW CATHEDRAL, VICTORIA, B.C.

WE illustrate this week the interior of the premiated design submitted in the competition for the above, by Mr. A. R. Scott, 19, Parliament-street, Westminster, under the motto "A.R.S." The plan, elevation, and exterior view have already appeared in our issues of June 3 and June 24 respectively. A notice of all the designs submitted in competition also appeared on page 620 of the BUILDING NEWS for May 20 last. The other designs were illustrated on May 27, June 3 and 10, and July 22. One of the premiums has been awarded to Mr. Scott, another to Mr. Wilson, of Regent-street, and the work to Messrs. Keith and Evers, of Victoria, as announced by us last month. As already stated by us, the author of this design studied the requirements, both in regard to site and the specified cost, more than any of the other competitors. He adopted an Early type of Gothic, with a certain ring of orthodoxy about it, relying for the effect which is to be obtained rather from the dignified proportions generally of our cathedrals, and that without the usual elaboration and enrichment.

BEECH HOLME STABLING, COLWYN BAY, NORTH WALES.

THE above work, which is picturesquely situated at the foot of the Pwllcrochan Woods, has recently been completed for Mr. W. H. Cogswell, of Calcutta, from the designs of Mr. T. E. Lidiard James, architect, 27, Chancery-lane, London. The materials used are red Ruabon bricks for facing, with dressings of best bed Cefn stone. The upper portion is in half-timber work, with red Broseley tiles and oak shingling for roofing. The internal fittings, which are very complete, are by Messrs. Musgrave and Co., the builder being Mr. J. B. Jones, of Colwyn Bay.

DRAWING-ROOM CHIMNEYPIECE, EAST QUANTONHEAD, SOMERSET.

THIS fireplace is one of several existing in Captain Luttrell's historic home overlooking the sea at Watchet. We gave a plan of the house as sketched by Mr. J. A. Gotch, F.S.A., in the BUILDING NEWS for August 26, when describing the visit of the Architectural Association. On that occasion Mr. John L. Robinson, R.H.A., took the photograph herewith reproduced. The whole of the chimneypiece is in plaster work,

with a panel of figures representing "Christ blessing little children." It is a typical piece of work, similar in design to much of a similar character in West Somerset.

THE ROOD SCREEN, DUNSTER CHURCH.

THE exterior of this grand church, with an interior detail, appeared in our issue for August 12, accompanied by an account of Dunster, its church, and castle. Mr. Robinson's photograph shows the exquisite screen which divided the parochial nave from the abbey choir. Mr. G. E. Street, R.A., renovated the fabric and restored this screen.

THE POWDER TOWER, PRAGUE.

(For description see article on page 614.)

AN AMERICAN NEW DRAWING-ROOM.

"FREE Classic in *extremis*" seems to be pretty clearly indicated by the latest phase of "advanced" design, which, from all accounts, is growing more and more popular among novelty-seeking architects, leaving the modest essays of the once fashionable "Queen Anne" style far behind with its ponderous dolorosities of form and colour. The rampant Rococo is to be the rage, and once again America, reflecting British taste, takes the lead. Whether this is the style affected most by the "architecture as an art" or "as a profession" party is not quite clear; probably the former, and, anyhow, the dash and go in the method typified by the interior herewith illustrated remain unquestioned. The architects of the drawing-room thus shown are Messrs. Delhi and Chamberlin, of New York.

THE WILLESSEN COTTAGE HOSPITAL.

THIS building, of which we give an illustration, and which is now being erected from the designs of the architects, Messrs. Newman and Newman, of 31, Tooley-street, London Bridge, is designed to accommodate nine beds—viz., four in the male ward, four in the female, and one in the separation ward. The wards are arranged upon each side of the central entrance; they are 20ft. long and 18ft. wide, well lighted, and ventilated upon the most approved principle. At each end are the offices, entered through a disconnecting corridor. Communicating respectively with the wards are, upon the one side, the matron's room, and upon the other a nurse's room. The bath-room occupies a central position in the corridor, and in the rear are the separation ward and operating room. At the extreme end of the central corridor, and disconnected from the main building, the kitchen is placed, surrounded by the scullery, pantry, larder, &c. Upon the first floor, over the front portion of the building, three bedrooms and linen room are provided, the same being approached from the entrance corridor. Externally, the building is faced with red brick and tile hanging, the gables and first floor being treated in timber framing and rough cast. The building is being erected by Messrs. Cowley and Drake, of Willesden Green, and the cost, when complete, will be £2,000. We understand that the building is arranged with a view to future enlargements, which, from the rapid growth of the neighbourhood, will apparently soon be necessary.

At a general meeting of the hon. the trustees of the Rugby Charity, holden at the Judge's Lodgings at Warwick, on the 24th inst., the trustees appointed to the vacant surveyorship of their Middlesex estate Mr. Charles H. Bedells, F.S.I., and Mr. C. Herbert Bedells, F.S.I., practising as architects and surveyors under the well-known firm of Lander and Bedells, at 6, John-street, Bedford-row, W.C. The estate, which consists of about 180 properties in the neighbourhood of Bedford-row, adjoins the larger estate of the Harpur Bedford Charity, which since 1882 has been under Messrs. Lander and Bedells' management.

At Monday's meeting of the Maidstone town council the technical education committee reported that they had received only two sets of plans for the proposed technical school, one under the motto "Efficiency," and the other under the motto "South Kensington." Mr. Wallis inquired whether there was not some understanding come to in committee that the plans should be referred to some eminent man in London. The town clerk denied this; under the conditions the "council do not bind themselves to accept any plan, and the selection may be made by themselves or professional or other assistants, and that selection will be subject to approval by the Department of Science and Art." The plans are open to inspection by members of the Corporation, and a decision will be arrived at to-morrow (Saturday).

AN AMERICAN NEW DRAWING ROOM. "FREE CLASSIC IN EXTREMIS."

WAYSIDE NOTES.

MR. H. O. CRESSWELL'S presidential address should be noted as a pleasant, instructive discourse, and one that put forward no unsettling theories and new-fangled ideas to lead to any radical choppings and changings, of which we have so much in this restless age. New presidents, unfortunately, so often imagine that they must be like the traditional new broom. Under a false impression that all the world and his wife expects a newly-elected president to champion trenchant reforms, and run amuck in the old pastures, such a one racks his brains for a new idea that may be applied either to the constitution or mode of conduct of the body over which he presides. This is a thing to regret, seeing that it so frequently leads to change for change's sake, the subversion of the old order, and the inauguration of novelty for its sake. It is all very well, when a new president conscientiously has some old conviction as to the best way of forwarding the interests of his particular society, that he should boldly proclaim his views even if generally unpalatable to members. In any other case a thoughtful address touching upon questions of the day in the aspect that they most affect the particular society is all that is expected of a president.

I should like not to be misunderstood in this matter, or to be believed to advocate either a stick-in-the-mud policy or a pig-headed conservatism. It is a duty to proclaim convictions when in a position of trust and honour, such as a chairman or president. Provided that all ideas are honest convictions, then the more the better. It is only ideas put forward for the sake of making novel suggestions, and being known as the maker of such suggestions, that are not required. As a writer of matter that has to come up to time, week in week out, I know it is constantly necessary to strive against the temptation to urge views that may appear new and effective in print, while at the same time making easy "copy." Unfortunately, we know that there is an immense amount of novel suggestion-making in every walk of life, particularly in political circles, where ideas are put forward, not for the benefit of the people, but the gain in notoriety to the individual.

Just now suggestions as to the grades of membership in the Institute may be good and to the point. Mr. Seth-Smith's proposal as to keeping the Fellowship for artistic members may be worth consideration. It has been suggested to me in another quarter—though, now I think of it, this may only have been the result of reading the letter you publish from Mr. Seth-Smith. Years back I advocated in these columns three grades in the Institute—Fellows, Associates, and Members. How should the "artistic" members be elected? "By acclamation," said a friend to me the other day. And a very good way this might prove. At certain times a ballot could be taken among all members for the election to the grade of Fellowship of a certain number of Associates, solely, however, on their merits as *designers of beautiful works of architecture*, and, be it observed, *such as have been carried into execution*. This should be a serious business and the result of polling the whole of the members—members here, of course, meaning Fellows, Associates, and the suggested Members. Perhaps it is doubtful whether the Members should have power to vote. In the case of three grades, the Members would be "undergrads," so to speak, and the great body of the Institute would be composed of Associates.

"It is the first step that costs," as the French architect said when he tripped over an odd and insulated riser at the head of the stairs—an afterthought—and fell down two "pairs" and landed in the sub-basement; and so the first inauguration of a scheme for three grades of membership in the Institute might be attended with some difficulty. Should the body of Fellows remain as heretofore, or should it dissolve and reconstitute itself? Providing that the Institute were agreeable to the latter arrangement, it would be the best; but, as there would probably be a precious to-do at any proposal of the kind, some other method would have to be followed. Unless the arrangement left the present Fellows as heretofore, and in the future added in the manner suggested, the only other course would seem to be

the creation of a sort of deified personage—a Superior Fellow—to whose ranks a certain number of ordinary Fellows could be elected by acclamation.

All this in case the Institute may intend any slight reorganisation. It may be that it could show all outsiders and all clamourers for new things that it knows its own business best. Doubtless it calls to mind, as we all do when outside opinion harasses us, the fable of the man, his son, and the ass, and will stand to its own guns for better or worse; in which case we cannot but look on and admire strength of purpose. As we half-expect, it may prove only to be Don Quixote and a host of rabble at the door of No. 9, concerning imaginary foes and enemies, while Sancho, in the form of the British public, ill-consents to follow the lead. Really, one makes these suggestions as to a select body of so-called artistic designers in the Institute; but what about those old members who, never having pretended to exercise cleverness in design, yet for solid worth as men and as architects, would weigh down a shoal of those who think so highly of their own attainments? Are they to play second fiddle?

This is the opinion of the Bishop of London on examinations, as given in a report of a distribution of prizes at Sion College:—"Of all means of attaining accurate systematic knowledge, there was none so good as passing through periodic examinations. An examination was one of the most potent instruments of teaching that could be devised. There was no instrument that really so disciplined the mind as to be carefully examined in what one had been previously studying."

Least pardonable of any faults in a competition is that of drawing a plan too large for the site. The grossest carelessness cannot account for such an error, and if there be "malice aforethought" in the planner, then he should be at once out of court. The whole art and the whole difficulty in the matter of planning to a certain limited area of ground lies in not overstepping the limits. It is often an easy matter to plan the required building with a few feet more space one way or another; and a very different affair to solve the problem and provide a certain amount of accommodation on a certain area. I do not wonder that there is a "Disgusted Competitor" in the Walsall Public Baths Competition.

Mr. Pearson will shortly have in hand the restoration of Rochester Cathedral. The success of the meeting at the Mansion House on Thursday may be greater or less; but at least funds sufficient for a commencement of works should be forthcoming at an early date. The scheme of restoration embraces the raising of the roofs of the choir, and its transepts up to the gables restored by Sir Gilbert Scott, and works of restoration and repair to the parapets and roof of the nave, and in the interior of the aisles and transepts. Besides this will be the "rebuilding of the upper halves of the two flanking towers, destroyed about 130 years ago," about which proposal something has been said, and about which we may hear more. We all know that ambitious schemes characterise the proposed restorations at Rochester—not necessarily referable to Mr. Pearson, but rather, I fancy, to the "authorities." A more definite term one cannot employ at the present juncture. Information as to the steps intended would be interesting to readers.

The engineers of the Totley Tunnel seem to be rather proud than otherwise that it is $3\frac{1}{2}$ miles long without a single air-shaft. It is to be hoped that they are going to make some later on. Shafts every 100 yards, about, as we find in, say, the tunnel on the line between Tunbridge and Redhill, may be unnecessary; but surely something is going to be done to ventilate this new three-and-a-half miles of blackness.

GOTH.

All visitors to Ilkley will be gratified to hear that the local board of that town have, subject to the approval of the Local Government Board, purchased the breezy moors surrounding the town, together with the picturesque fall known as Hebers Ghyll, from Mr. Middleton, the lord of the manor. The moors include an area of over two thousand acres, and the price to be paid is £14,000.

THE POWDER TOWER, PRAGUE.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THIS rich and picturesque tower is one of the most remarkable architectural monuments in Bohemia, handed down from the middle ages. The town council of the royal city have just issued a comprehensive folio fully illustrating the building, with an account of its history and recent restoration, which has been carried out at the expense of the Corporation. The burgomaster has officially sent us a copy of the work with a permit to reproduce any of the plates, so that our readers may be made aware of the publication, for which Mr. Bernard Quaritch, of Piccadilly, is the sole agent in London, and the price is £2 per copy. We give a plan and two elevations to-day, and at an early date intend to illustrate some of the sections. There were formerly 22 towers in Prague, now there are but three, all the others having been destroyed by fire, war, and time. Most of them formed part of the 13th century city walls, and many a bloody deed has marked their history. Mathieu Reysek is said to have been the architect of this tower. Its renovation was commenced in 1875 and terminated in 1886, under the direction of Mr. Joseph Mocker, the architect. The professors of the University of Prague, aided by Mr. W. W. Tomek, Councillor of the Government, and Dr. Joseph Emler, city librarian, helped the architect in the production of the work. Mr. Antonie Tatoun, town engineer, gave his services. The statues of Charles IV. and his son Wacsalv figure in the niches over the entrance, with others of royal personages, such as Wladislav II., Georges de Podiebrady, Premysl Otakar II., and the Emperor Charles. Mr. Tomek's history of the tower given in the volume before us supplies much special information of interest to the archaeologist. This was known as the *Porte Nouvelle*, as it replaced a more ancient fabric. Charles IV. originally erected these towers to employ his starving subjects about 1353. Of this period are the black tower, and white or round tower, which served as a State prison where prisoners of rank were confined and frequently executed without trial. The Daliborka still embodies parts sufficiently perfect to give a good idea of the horrors of a Mediaeval prison. Mention appears in the municipal records concerning this tower as early as 1310. All the upper part above the parapet is new, as shown by our plate to-day; but, with the exception of the statues and arcades, which have been renewed, all the main fabric is ancient. Mr. Mocker has given drawings of the building as he found it before commencing his work of restoration. The volume is contained in a strong portfolio, and the printing, as might be expected, is worthy of the memorial undertaking.

CHIPS.

At the last meeting of the Llandudno board of commissioners, it was decided to obtain a report from Mr. John T. Wood, C.E., of Liverpool, on the scheme for the improvement of the sewerage of the town prepared by their surveyor, Mr. E. P. Stephenson, C.E.

On Saturday the foundation stone was laid of a mission church, to be called St. John's, at Caldergrove, in the parish of Crigglestone. The edifice, which is to be erected from designs by Mr. Swinfen Barber, of Halifax, is in the Early English style, and will accommodate 150 persons.

The memorial stone of a church which is being built for the United Presbyterian Church at Wardie, N.B., was laid on Saturday by Professor Calderwood. The church, which will seat 500 people, and is to cost £2,700, will be in the Middle Gothic in style. There will be no gallery, but the design will provide for the erection of one should it be needed. Mr. John McLachlan, York-place, Edinburgh, is the architect.

The corner stone of the new class-rooms, cloak-rooms, &c., about to be added to St. Thomas's Church schools, Stanningley, near Leeds, was laid on the 15th inst. The architects are Messrs. Jowett Kendall and J. Harper Bakes, M.S.A., of Leeds, and Messrs. J. Thornton and Son, of Idle, are the contractors. The work is estimated to cost £1,463 2s.

On Tuesday week the Earl of Durham opened a new parish hall for the parish of Penshaw, in county Durham. The building is in the Queen Anne style, executed in red brick and stone dressings. The hall will accommodate about 300 persons, and has cost about £650. Mr. Geo. Oates, builder, Penshaw, has carried out the work from designs of Mr. J. Gibson Cowe, architect, Fence Houses.

THE CAMERA CLUB.

THE Camera Club have a choice show of photographic pictures of the year now on view in their reading-room, which well maintains the character of their exhibitions. The subjects are chiefly of landscapes and portrait studies, with very few of an architectural interest, though Lieut. C. E. Gladstone, R.N., sends a charming detail picture of an old staircase from Mont St. Michael, and a street view in Caen, with the Renaissance spire of St. Pierre in the distance seen in full sunlight against the sombre shadow of the narrow thoroughfare in the fore part of the composition. Mr. Richard Keene contributes the doorway of the banqueting hall at Old Moreton Hall, an ever-interesting specimen of English timberwork. He likewise sends "Salisbury Cathedral from the River." The series by Mr. Shahpoor N. Bhedwar, illustrating the ordination of a youth as a Parsee priest, shows a reliable rendering of the Yacna ordinal not hitherto available to ordinary mortals. The youth passes through the "Invocation" and then the "First ablution," kneeling quite nude before the chief priest. The "Initiation" follows, then the first officiation of the novice, and at last, to use the words of the catalogue, "A Full-blown Priest" appears feeding the sacred fire, having acquired the ability of reciting the Avesta thoroughly and become acquainted with the secrets and philosophy of his faith. Mr. Ralph W. Robinson has a set of admirable pictures, the first of which shows a pair of "Young Vagabonds," which is a very fine study, all the detail of the photograph being concentrated on the boys' faces and figures, with the old cart and other accessories in a secondary rendering, subservient to the main idea of the print. The "New Pet" may be taken as a typical instance of Mr. Robinson's mastery over light and shade in his photographs without loss of necessary detail. Mr. Harry Tolley shows views from Killarney, and Mr. Van der Weyde exhibits the results obtained by an artistic use of the "photo-corrector," by the means of which the needlessly large scale of heads, hands, and feet is proportionately modified to agree with life.

THE RUABON BRICK AND TERRACOTTA COMPANY, LIMITED.

WE have before us the newly-published catalogue of this company, which in point of size and comprehensiveness exceeds other publications of the class. It is a large folio volume of 100 plates illustrating moulded bricks for one, two, and three courses in height, jambs, strings, and other purposes. Lintels, bands, panels, diapers, cornices, copings, balustrades, pilasters, brackets, chimney stacks, terminals, finials, and a variety of other details are to be found, and these are all drawn to full size. Every architect must have found the need of a book of this kind in enabling him to specify brick and terracotta mouldings and patterns which are in stock. The Ruabon Company acknowledges the assistance of Mr. Alfred Burr, F.R.I.B.A., of Gower-street, in the preparation of this catalogue. From a general glance over the plates we find many artistic designs and patterns, and as these, as in the course-mouldings and panels, can be disposed in different ways, many combinations are possible. Thus it is easy to combine many of the moulded courses to form bands and cornices. The value, too, of making the mouldings and ornament to suit the height of the brick courses has been recognised, and all the patterns are obtainable to suit the various heights and number of brick courses. All the most useful mouldings, like cavettos, cyma-rectas, toruses, and their combinations, are to be found in the early plates, and not only Classical, but Gothic, mouldings are introduced in great variety of patterns. Simple splayed and moulded jambs for 4½-in. reveals follow. The two and three-course moulded brick patterns are suitable for cornices, and for fine members half-course moulded bricks are illustrated. A very useful series are the patterns of dentils for one and two courses and half-courses, and the ornamental brick bands and jambs. The Company have studied architects' wants in the matter of key-stones, and stops to chamfers, or angle hollows for jambs, many examples of which are given. The ornament varies in merit. For diapers, and bands of two, three, and more courses in height, we refer the reader to plates 24 to 40. In some of these plates treatments of

single courses in three-course bands may be seen; also ornamental squares for brickwork of four and five courses. The designs for pilasters, caps, and bases are suitable to large or small buildings, these being also regulated by the courses of brickwork. Mullions and transoms, oriels and bay-windows, showing the jointing of mullions, cornices, and corbellings, arches and lintels of terracotta are useful examples of treatments, and the plates illustrating chimney-stack construction, gables, gateways, shop-fronts, façades, and other suggested treatments are of value to the profession, and make the Ruabon Brick and Terracotta Company's catalogue a useful book of reference.

WORK-A-DAY ART.

A LECTURE on the dignity of craftsmanship was given under the title of "Work-a-Day Art" last (Thursday) evening at the Polytechnic Institute, Borough-road, S.E., by Mr. Lewis F. Day. Mr. T. Buxton Morrish occupied the chair, and after the delivery of the address the art rooms were thrown open for inspection.

Mr. DAY said that the very existence of a Polytechnic Institute like the one in which they were assembled was evidence that labour, and the dignity of handicrafts in particular, were beginning to be recognised. Not long ago, and he feared the time was not yet altogether past, respectability was measured by a man's keeping aloof from manual labour. The reaction against this foolish notion had set in. Common sense and common manliness had always resented the *prestige* attached to doing nothing in particular, even though the *élite* might do it very well; but that resentment now found fuller expression, one of these forms being in polytechnic institutes and the demands for technical education. Perhaps in this awakening to the value of handwork and the importance of the handworker, there was just the danger of overlooking the fact that manual labour was not the only work worth doing. The thinker was also worthy of his hire, and the future of craftsmanship, the hope of the craftsman, lay in the association of brain-work with handwork. That, he took it, was the cause and intent of institutions such as that polytechnic—to help the worker to use his head as well as his hands, and so labour to better purpose. After all, it was not by polytechnics that the workman would save his soul alive. His future rested with himself. It was for him to make full and proper use of the facilities so much more readily afforded than ever they were to his forbears, and it was with the hope of helping him to help himself that he, who claimed also to be a workman, was talking to him that evening. The artisan was emerging from some of the obscurity into which he had fallen; but it was well to ask whether there was not some reason for his disrepute. It could not be denied that some who claimed the name of working man had done it in vain. If all artisans had been workmanlike, the bitter taunts against the British workman would never have been uttered. The true workman had a better answer to calumny than indignant protest, by giving it the lie direct in every stroke of his work. Perhaps some of the popular failure to understand how nearly allied handicraft was to art was because workers had not made it clear enough that their work was worthy. Their business was not to make any pretension to being artists, nor to give themselves airs of artistic superiority; but just to show by their work that a handicraft was worth following, and that craftsmanship in its fullest development rose to the dignity of art. To call handicraft "fine art" was not to dignify it, but simply to misuse words. It was not what a man styled himself, but his gift, his genius, that made his work art, and made that art sometimes a fine thing. It was a misfortune for handicraftsmen that their ambition was apt to get twisted into gauging success by its money value. It was a fine thing that our walk in life should do us credit, but a much finer thing that we, by our work, should raise and dignify our calling. A good workman could be recognised by his modesty and his pride—by his modesty in his work and opinion of his work, by pride in his lofty ideal and aim. Mr. Day passed on to refer to the delight ever felt in making any one thing well, observing that, by comparison, selling was a sordid pursuit, buying an idle one, but in making, man was at his best and manliest. What, he asked, should be the ideal of the craftsman? Not making money, not

rising in the social scale, but turning out the best and most perfect work. The ideal could not well be too high; but it should not be too far off, or the worker would despair. He would set stages to the ideal of every craftsman. One of these was the proper use of every tool handled and of every material on which he had to depend; to acquire the proper use of his hands was a long stage on the way towards good work, and could be attained by everyone possessing health and honesty of purpose, and from thence to the mastery of his craft was a further and important stretch, short of which no man should rest satisfied. But a man should go farther still, and should take advantage of every opportunity of training himself, not only in his craft, but all round. His aim in his work should be precise and definite. "Know what you are to do, and do it," was Turner's saying. Having done it, a man would want to do more if he had it in him. Good work was not mere mechanical precision. In some mechanical manufactures precision was all-important, but they scarcely came under the title of handicraft. In decoration, on the other hand, it was easy to over-estimate the value of precision, for, if too closely followed, this precision took all the life and interest out of work. The lecturer urged that while a workman must express his own ideas in his own way, he should first of all make himself acquainted with the work of others, and must not be wanting in respect for their work and their ways. A man should learn both in school and in workshop, and should endeavour to profit by both; in the former the theory of work was taught, and in the latter its practice. Neither was experience alone. The ideal training would be in a workshop where the rule was good work under the guidance of professors who knew, and of master workmen who could do; where craftsmanlike rivalry took the place of commercial competition, and thrift the place of cheapness; where the one aim was to teach the young idea good work and how to do it.

LATERAL OBSTRUCTION OF LIGHT.

A VERY frequent cause of complaint made by the owner or tenant of a house which stands some distance back from the line of frontage, is the interception of light and prospect caused by the erection of a shop in front of the adjoining house. In many of the suburban roads in the Metropolis, where front courts and gardens exist, this kind of obstruction has become very vexatious, the adjoining owner's property being seriously affected thereby. The Metropolitan Building Act permits the erection of front shops of one story in height, as we see in many thoroughfares. Edgware-road and Euston-road may be mentioned as showing examples of this kind of erection, and of the injurious effect of permitting shops to be brought out to the roadway. The London County Council would be earning the gratitude of residents and the public generally by prohibiting the construction of shops beyond a reasonable limit of the front areas. If a row of houses is set back from the roadway, say 30ft.—which many are found to be—and one owner or lessee extends his frontage for shop premises to the roadway, it will be at once seen how injuriously the adjoining houses are affected, how much light and prospect the erection would cut off. The obstructed premises, in fact, become no longer habitable for private residents, and the consequence is that before many years the whole row of houses have to be advanced to the same line. But if there was a by-law which permitted only one-half or less of the depth of the front garden or court to be so built over, the adjoining occupiers would have a wider prospect from the windows, and the angle of view and of light would be greater.

Our remarks receive additional force from the report of a case tried at the Cheltenham County Court before Judge Ellicott, "*Woodward v. Moulder*," and reported in our last issue. It was an action to recover £50 damages for an alleged obstruction of light. Up till recently the tenements in question were held by one owner; they stood some distance back from the road. The properties were sold, one to plaintiff, and the other to defendant. The latter built a shop on the front land 24ft. deep, 17ft. wide, and 11ft. high, which considerably intercepted the light received by the plaintiff. The evidence called for plaintiff showed that rather more than half the window was affected

by the shadow thrown by the wall, which would appreciably darken even the middle of the room. The defendant pleaded that the obstruction was only lateral, and merely affected a small part of a single window. An examination of the premises was made, and the judge decided that there was an appreciable diminution of the light, and that the house was less commodious than it was, and the damage was assessed at £30. In this decision the judge said the former common ownership of the houses did not affect the question. It makes no difference whether the owner sold two houses to different persons or only one house and adjoining land; in neither case is the purchaser of the land, with or without the house upon it, entitled to build so as to obstruct the ancient lights of the adjacent house—a wholesome and just law. This law of prescriptive right of light and air appears to be the only protection that an adjoining owner has against a building-owner who has no consideration for his neighbour. The local authorities apparently did not make any objection to the erection of the shop, nor does any local by-law we know of prohibit the erection of such a building on the front area. The subject is one that becomes more pressing every year both in provincial towns and in London. A local by-law limiting the bringing out of such buildings in cases where there is a considerable area in front, and in other cases of prohibiting such erection, is called for in the interests of owners and the public. Lateral obstruction of a window does not appear to have been always considered in these erections. The adjoining owner has to prove by evidence there is an appreciable diminution in the light entering his front room, but it may be sometimes difficult to do this, as the principal light enters the window above the one-story building. Thus it often happens that the adjoining and aggrieved owner cannot prove a substantial injury by this means, and although his property has greatly suffered, and his front room on the ground floor is spoilt entirely by the hideous blank wall of the adjoining shop. Local authorities should, therefore, have some power to limit lateral obstructions, which project beyond the windows of adjoining houses, and which reduce a very appreciable angle both of prospect and light.

CHIPS.

The local board of New Swindon have decided to purchase the local gas undertaking at a cost of £51,400.

The business of patent glazing and zinc roofing hitherto carried on by the late Mr. Helliwell will be continued as usual under the style or title of Helliwell and Co. by the acting executors, Mr. J. Boosie and Mr. W. Kemp, both of whom were associated with the late Mr. Helliwell in the conduct of the business for many years.

Mr. A. P. I. Cotterell, A.M.Inst.C.E., has been called in to prepare a new scheme of sewage disposal for the town of Milborne Port, Somersetshire.

A new clock at Purston, near Pontefract, has been fixed on the Junction Hotel at the junction of the Purston, Ackworth, and the Pontefract highways. Messrs. Potts and Sons, of Guildford-street and Cookridge-street, Leeds, are the makers.

The endowed school, Frodsham, is being warmed and ventilated by means of Shorland's patent Manchester grates, exhaust roof ventilators, and inlet-tubes, the same being supplied by Mr. E. H. Shorland, of Manchester.

The east window of the parish church of St. Michael, Brent Knoll, Somerset, has just been filled with stained glass. The principal lights are occupied by the three Archangels. St. Michael is represented in the centre with a spear, in the act of treading upon the dragon. St. Raphael as a pilgrim, while St. Gabriel bears the lily of the Annunciation, and the first words of his message, "Ave Maria," on a scroll. Under these are represented smaller accessory figures in medallion panels. The work has been carried out by Messrs. Wailes and Strang, of Newcastle-upon-Tyne.

Among the Parliamentary projects for next session is one to be known as the East Fife Central Railway. The line is to start from Leven, and run past Dunifene on to Kennoway. From thence it goes past Balgrummo, Burnside, Netham, Nether Pratis, on to Bonnyton, where a junction is to be formed. The one line branches off by Teuchats on to Ceres, and proceeds on to Dairsie, where it joins the present main line. The other part goes by Gileston Mains on to Largoward, Lochty, and Stravithie, where it joins the present Anstruther and St. Andrew's Railway.

Building Intelligence.

COVENTRY.—The foundation stone of the public baths was laid by the Mayor on Thursday in last week. It will be remembered that in the competition for designs Mr. Harold T. Burgess, a pupil of Messrs. Spalding and Cross, architects, of London, won the first premium of £100, and his plans were accepted by the Baths Committee, though, on account of his not having attained his majority, his employers were appointed joint architects with him. The baths are situated in Priory-street, and the accommodation to be provided will be three covered swimming baths, each 90ft. by 35ft., a plunge bath or "soap hole," ten first and twenty second-class men's private baths, and four first and six second-class ladies' baths, superintendent's residence, with offices, a boiler-house, laundry, drying-room, &c. The building will have a frontage of 132ft., and a depth of 236ft. The front block will comprise offices and superintendent's residence. There are separate entrances for ladies and gentlemen, with pay-office between. All the bathing accommodation is provided on the ground floor. The three swimming baths are behind the front block. Two will be spanned by separate iron roofs, and the third by a wooden roof, and each will be inclosed by walls. Fifty dressing-boxes will be provided for use in connection with each of the first-class swimming baths, and fifty-eight for the second-class bath. The chief front will be faced with best red bricks, with Portland stone dressings. The staircases will be of concrete. The internal walls, and the inside of the swimming and plunge baths will be faced with glazed white bricks with lines formed of bricks of another colour. All passages and floors to the front block, boiler-house, and laundry will be fire-proof. Mr. C. Gray Hill is the builder, his contract amounting to £16,380.

EDINBURGH.—The new chancel added to St. Paul's Episcopal Church, York-place, Edinburgh, was recently dedicated. The church, as originally designed, consisted of a nave, north and south aisles, and a short chancel 15ft. long. The nave consisted of five bays of a total length of 78ft., with a gallery over the entrance at the west end, in which was placed the organ. The galleries were continued over the aisles, with access stairs flanking the main entrance at the west end. In carrying out the alterations, the architects, Messrs. Kinnear and Peddie, have kept in view, as a guiding principle, the preservation of the original features of the church as far as possible. In designing the new chancel, the original east termination of the church has therefore been preserved, merely extending it by the distance required for a chancel in keeping with the length and other proportions of the nave. The galleries have been removed and the space formerly occupied by the stairs added to the nave, which is now one bay longer than before. The new chancel is equal in length to three bays of the nave, about 50ft., and the organ is now placed in a bay next the nave, with stone piers and arches opening to the chancel and the south aisles. Beyond it is the clergy vestry, and below is the choir vestry. Under the chancel there is a choir room. The church has been re-seated, and oak choir and clergy stalls have been placed in the chancel. The glass of the original east window has been transferred to the west window, and the east window and south-east chancel window have been filled with stained glass by Messrs. Heaton, Butler, and Bayne. The organ has been reconstructed by Messrs. Bishop and Son, London.

KIDDERMINSTER.—The Countess of Dudley on Saturday laid the foundation stone of the new nave and chancel of St. John the Baptist's Church, Kidderminster. The existing church, an unhappily-coloured edifice, built in 1843, of Broseley bricks, will be partly merged in the new buildings, and the present nave will become a south aisle of the future structure. On the north of the present building there will be a lofty nave, with chancel, and a new north aisle will flank the new nave, and add to the proportions and accommodation of the church. Mr. J. A. Chatwin, of Birmingham, is the architect. The work has been divided into sections, the first being the erection of the new nave, north aisle, and west porch. The contract for this work is £4,565, and it has been entrusted to Mr. T. Collins, of Tewkesbury. The second portion of the work, which will include the chancel, north porch, and

vestries, will, it is estimated, involve a further expenditure of £2,548 10s. The new building is to be erected with Alveley stone, and the remaining parts of the old structure will also be cased externally with the same material, and thus give harmony to the whole.

LEEDS.—Extensive alterations are about to be carried out at Oxford-place Chapel, from plans prepared by Mr. G. F. Danby and Mr. Wm. H. Thorp, architects, of Leeds, at an expenditure of about £3,000. The chapel now provides seating accommodation for about 2,000 people. The front facing Victoria-square is to be entirely remodelled. The central portion of the façade is to be slightly projected from the main block of the building. It will be surmounted by a pediment rising above the main eaves cornice, which will be supported by three-quarter columns, with capitals, and entablature of the Ionic order. Flanking the pediment on either side are to be cupolas. These will be carried out in masonry and brickwork, with domed roofs of wood, covered with lead. The main angles of the building are to be treated with rusticated quoins in alternate courses of stone and brickwork. A Venetian window of three lights will form the central feature on the upper story, and circular-headed single windows, will be ranged on either side. An additional double entrance will be provided in the centre of the façade, the doorways to be surmounted by an entablature and carved pediment, supported upon projecting columns with Roman Doric capitals. It is also proposed to improve the blank walls by providing a new eaves cornice, a moulded string-course at the first floor level, and also new windows. The work will be executed in local faced bricks of a deep red colour. The dressings will be of stone. The style will be the English Renaissance of the Wren period. The interior of the chapel is also to be remodelled. New and wider entrances will be made to the area, where the whole of the deal pews will be replaced by modern seating, executed in pitch-pine. The existing mahogany pulpit is to form the central feature of a rostrum. The seating accommodation in the gallery is to be improved. The whole of the windows in the building will be reframed and reglazed, new heating apparatus introduced, and a Boyle's air-pump ventilator provided.

LEIGH WOODS, BRISTOL.—The new church of St. Mary, at Leigh Woods, built at a cost of £4,000, was opened last week. The contract has been carried out by Messrs. R. Wilkins and Sons, of Bristol, from plans by Mr. John Medland, of London. The church is in the Early English style. It is constructed of Pennant stone from Stapleton, with freestone dressings. It consists of a simple nave, without aisles or pillars, and a chancel apse-like in form. The nave is lighted by deeply recessed dormer windows, placed between the principals of the roof. The roof is of open timber work. The floor is laid with pitch-pine blocks. At the north-west corner is a recess to be used as a baptistery. In the chancel over the altar are three windows, filled with stained glass, representing scenes in the life of Christ, and executed by Mr. W. G. Reid. The floor is paved with plain and ornamental tiles. There is an organ chamber on the south of the chancel, but at present it is unoccupied. The seating for the congregation consists of specially made rush-bottom chairs, and that for the choir and clergy of oak benches. The pulpit, lectern, and altar table are also of carved oak. The warming is by hot-water pipes. There is a large vestry on the north-east side of the church, which will also be used as a parish room. All the doors are of oak, with hinges and other fittings of wrought iron.

MANCHESTER CATHEDRAL.—The levelling of the entire floor of the nave of Manchester Cathedral is at last completed. All the former sittings in the centre and north side of the nave, and all the pews in the Trafford Chapel and in Brown's Chapel, on the south side, have been cleared away. In the centre the space has been covered with chairs, and a similar course will be taken on both the north and south sides. The new south porch is also practically completed, while the new baptistery chapel, at the south-west end of the nave, is on the eve of completion.

OXFORD UNIVERSITY MUSEUM.—A large addition is being made to the University Museum for the department of Human Anatomy. The extension is on the east side of the main building abutting on the parks, and the main entrance is on the north front. In the basement there is a

tank-room, 60ft. by 29ft., a working lobby, 5ft. by 21ft., inspection-room, preparation-room, coal-cellar, attendant's rooms, general stores, and the usual offices. The principal rooms on the ground floor are the dissecting-room, 60ft. by 30ft.; museum, 30ft. by 40ft., two private rooms, vestibule, prosecutor's room, and a lecture theatre, the latter being 30ft. square. The museum has a gallery running all round at the height of 11ft., and both that and the dissecting-room receive light through the roof from the north side only, to avoid the glare of the sun, Rendle's patent system of glazing being used. The microscopical room, which is 18ft. by 30ft., is on the first floor, where there are also two assistants' rooms. At the north-east angle of the building is a large lantern over the lecture theatre, together with a ventilating shaft, and the principal features in the north elevation are the octagon turret, and the gables and dormers over the windows. The chief decorative work, however, is the window lighting the museum in the east elevation, some handsome balustrading being also placed round the lecture theatre. The stone is Box Ground from Bath, and pugging is used between the principal floors to deaden the sound. The builders in charge of the work are Messrs. Symm and Co., the architect being Mr. H. Wilkinson Moore, Beaumont-street, and the clerk of the works Mr. R. England.

ROCHESTER.—A meeting in aid of the Rochester Cathedral Restoration fund was held at the Mansion House, E.C., yesterday (Thursday) afternoon. The chair was taken by Alderman Davies, the member for Rochester, and the speakers included Earl Stanhope (Lord Lieutenant of Kent), the Bishop of Rochester, and Dean Hole. The restoration now in progress was initiated many years ago, and in part carried out under the supervision of the late Sir Gilbert Scott. The members of the Chapter have found funds for a considerable amount of work done in late years; but unfortunately there is no special fabric fund, and a public appeal is now being made in order that the work may be continued under the advice of Mr. J. L. Pearson, R.A. A few years ago the west front was found to be in a perilous condition demanding immediate underpinning repairs. These are in a fair way of completion, and it is proposed to rebuild the upper portions of the two flanking towers destroyed about 130 years ago. The scheme includes the raising of the roofs of the choir and its transepts up to the gables which Sir G. G. Scott restored. It includes, also, works of reparation and restoration in the parapets and roof of the nave, in the interior of the aisles and transepts and elsewhere.

STEPNEY.—The new church of St. Philip, Stepney, was consecrated yesterday (Thursday), by the Bishop of Wakefield. It has been built from plans prepared by Mr. Arthur Cawston, at a cost of £40,000, entirely borne by the vicar, the Rev. Sidney Vacher. It replaces an old edifice, built in the Debased Perpendicular style of the early part of this century, and consecrated in the episcopate of Bishop Howley. The new church is on a large scale, cruciform on plan, with apsidal eastern termination, and is built of red brick, with Ancaster stone dressings. The style is Geometrical Early English, and it has a clerestory, triforium, and vaulted roof. Beneath the church is a large, light, and dry crypt, which forms a series of halls and vestries for parish purposes. Amongst them is a depot for outfits for emigrants.

A Local Government Board inquiry was held on Wednesday week at the Guildhall, Dartmouth, by Mr. T. Codrington, M.L.C.E., relative to the Town Council's application for permission to borrow £6,000 for water supply works, and £650 for works of sewerage. The borough surveyor explained the details in the plans.

The reconstructed Potter Bridge, Reydon, on the road from Southwold to Wrentham and Lowestoft, was opened for traffic last week. The new bridge stands on a foundation of concrete, with brick abutments and wings. The superstructure is of steel girders with buckled plates between, the whole being covered with concrete. The parapets are formed of cast-iron standards and wrought-iron rails, with brick piers and stone copes. The width of the roadway is 18ft. and the water-way is 14ft. The bridge was designed by, and its erection carried out under the superintendence of, Mr. H. Miller, County Surveyor, the work of construction being done by Mr. W. J. Chilvers, of Wangford, the steel portions being supplied and fixed by Messrs. Knights and Stacy, of Harleston.

Engineering Notes.

THE CORNWALL RAILWAY.—The Great Western Railway are proceeding with the doubling of the Cornwall Railway. Tenders were recently invited for laying a second line of rails over the $4\frac{1}{2}$ miles between Par and St. Austell. That contract has now been let to Mr. Strong, contractor, for about £7,000. Specifications and drawings are now to be seen at the offices at Millbank, Plymouth, for doubling the line between Liskeard and Lostwithiel—about $14\frac{1}{2}$ miles. The tenders for this section are to be sent in by the end of October, and it is stipulated that the work shall be completed within twelve months. There will then remain the short section between Lostwithiel and Par in the way of a clear run from Liskeard to St. Austell. Here, however, there is a wooden viaduct to be rebuilt in stone.

DORE AND CHINLEY RAILWAY.—The Topley tunnel of the Dore and Chinley line of the Midland Railway, which will connect Manchester and Sheffield by a better route, was pierced on Sunday evening, when the men working from the Sheffield side met those engaged in the work of excavating from the Padley Woodend. The tunnel will be the longest in the British Isles, with the single exception of that under the Severn. It is 6,200 yards long, or over three and a half miles, and its working has taxed all the resources of engineering skill. The difficulties of setting have been exceptional. There are only four shafts, all situated within the first three-quarters of a mile. The remaining distance of two and three-quarter miles is at present without a shaft. In spite of this difficulty, which was increased by the fact that the height of the hill over the tunnel is, at its summit, 750ft., and 1,360ft. above sea level, a tunnel has been made straight from end to end. The work has been greatly impeded by intrusions of water, as the strata through which the boring took place favoured flooding. The tunnel, the roof of which is 20ft. high above the rails, is 27ft. broad, and will accommodate a double line of rails. It is being lined with brickwork. At one portion of the Padley end stone was available, and was used for the walls, bricks being employed for the roofing arch. A culvert runs from end to end. The gradient rises from the Sheffield side, so that a train at the Padley end will be 76ft. higher than one at the Topley or Sheffield mouth. Most of the work has been carried out by air-drilling apparatus, the air being conveyed in 4in. pipes, and, as it escaped, affording ventilation for the workings. The Cowburn tunnel, two miles in length, will be finished this year, and it is expected that the whole line from Dore to Chinley will be opened for goods traffic about 12 months hence.

COMPETITIONS.

ROTHERHAM.—The designs submitted by Mr. Richard J. Lovell, of 46, Queen Victoria-street, E.C., for the Rotherham public baths have been placed first, and those of Messrs. Magnall and Littlewood, of 29, Brown-street, Manchester, are awarded the second place. We hope to illustrate the chosen design at an early date from the architect's drawings, which have been promised us.

STOCKTON-ON-TEES.—At a special meeting of the School Board for Stockton, held on Monday, the Higher Grade School Committee recommended, on the advice of Mr. E. R. Robson, F.S.A., architect to the Education Department, the adoption of the plans of Mr. J. M. Bottomley, of Middlesbrough, for a higher grade school. This was agreed to; but it was decided to obtain tenders for the main building only at present, and to omit the two wings. The cost of carrying out the plans in their entirety will be about £20,000, exclusive of the outlay on the site (£6,500). The cost of the buildings, exclusive of the site, was originally estimated at £10,000 by the board.

ST. SAVIOUR'S, SOUTHWARK.—In the competition (limited) for new baths and washhouses, St. Saviour's, Southwark, the following were the competitors:—Messrs. Spalding and Cross, Messrs. Harnor and Pinches, Mr. Elkington, Mr. A. Hessel Tiltman, and Mr. Fras. J. Smith, of 17b, Great George-street, S.W. Mr. Fras. J. Smith's designs have been selected. We have not heard how the second and third premiums have been awarded.

Correspondence.

MOTTISTON MANOR HOUSE ILLUSTRATION.

To the Editor of the BUILDING NEWS.

SIR,—Among the medley in Mr. Norman Shaw's book, Mr. Reginald Blomfield figures, I see, as a trenchant essayist, aiming ostensibly at truth in art, midst a "disingenuous," "unlicensed abuse" about the "impertinence" and the "bathos of professionalism" which darkens the door of the "orthodox professional head-quarters" in Conduit-street, where art and science meet together and business proficiency is guaranteed by Royal Charter. All this tall talk contributes but little really to anyone's information, though, underlying much of the high-falutin, are a few truisms, such as the undoubted advantage of sketching constantly good specimens of old work. Mr. Blomfield's own sketch of Mottiston Manor House, which you published last Friday, shows that he can draw, no doubt, with dash and feeling, if without any idea of distance in colour. The unfortunate part of his drawing, however, is its absolute disregard for hard facts; indeed, the relative proportion of things is as over done here as in his writing. He pretends to give a truthful view of the house among a series of old buildings from the Isle of Wight. The plan and elevation given below his sketch show at once how entirely misleading and incorrect it is. The east elevation gives the relative heights of the main building and the wing, the latter being much lower than the former. Mr. Blomfield, correcting works of the past as he goes along, alters all this, dodging in some darker shading in the upper part to modify the alteration. If he had not pretended that this sketch actually represented the house, no one could blame the draughtsman, but he has allowed his craze for art seemingly to tamper with his rectitude, making his study profess to be what it actually is not. Is professionalism answerable for this?—I am, &c.,
AN OLD TREE SQUARE.

EPITAPHS.

SIR,—I send you the following on Mr. Nightingale, Architect:—

As the birds were the first of the architect kind,
And are still better builders than men,
What wonders may spring from a Nightingale's mind,
When St. Paul's was produced by a Wren.

Another, which, I think, is better known, is at Gateshead, and erected apparently to the memory of another architect:—

Here lies Robert Trollop,
Who made yon stones roll up;
When death took his soul up
His body filled this hole up.

This man was the architect, it is said, of the Exchange and Town Court of Newcastle.

Was it not Pope who wrote the epigram on Sir John Vanbrugh?—

Lie heavy on him, earth! for he
Laid many heavy loads on thee.

I don't know whether any other architects have been thus permanently recorded, if so perhaps some of your readers may be able to acquaint us.—I am &c.,
October 20. Ed. A. JOLLYE, A.R.I.B.A.

WALSALL PUBLIC BATHS COMPETITION.

SIR,—I wrote to the Walsall borough surveyor, Mr. H. Middleton, on the subject of the proposed public baths, and drew his attention to the statement in your last week's issue, that the selected architects in this competition had none of them complied with the conditions of the competition. Mr. Middleton has replied to me this morning that the statements in the papers are incorrect.

There is, therefore, some mistake one side or the other, and the only solution to the doubt will be for the council to publish the three selected designs.

I wrote to the town clerk on the subject, and he has promised to put the matter before the town council.

I shall be glad if you will insert the above information in your next for the benefit of the competitors in this competition.—I am, &c.,
October 25. A COMPETITOR.

SIR,—As a competitor in the above competition, and also one who has complied strictly with the

conditions of the competition, to say the least, it is most discouraging to know that the selected designs are not the best of those sent in, and also that none of the selected designs have fulfilled the conditions of the competition. If this statement is not correct, it is clearly the duty of the Council to remove all doubt at once.

There were 25 sets of plans sent in, and taking six weeks as the time spent by each competitor with an ordinary day's work of ten hours per day, at the very low rate of, say, 2s. 6d. per hour, brings out the cost of one set to £45, so that £1,125 of labour has been spent upon these designs—considerably more than the proposed cost of the entire building.

It is affirmed that:—1. Two of the three premiated designs will not go on the land, the first encroaching on the land reserved by the council for the erection of shops. 2. The design placed third takes in 3ft. of land on the left-hand side of the site. 3. Neither the first nor the second designs has separate entrances to the female slipper-baths. 4. There is only one entrance to design No. 1, over which coals and everything have to be taken. 5. No provision for replacing the boilers is made.

If the above are facts, then there has either been some unfairness, or there has been gross negligence in the selection of the best designs. On the other hand, if the whole thing is a misrepresentation, then it can be put right at once by publishing the selected designs in one of the building papers, which I have already suggested should be done.

I am sure all architects who are in the habit of going in for competitions do not mind being beaten, providing the successful man has produced something better. But if an inferior design is adopted, it is not only unfair to the competitors, but detrimental to the interests of the Walsall ratepayers.—I am, &c.,

H. W. R.

"BRICKS."

SIR,—I am indebted to Mr. Wm. Theobalds for his letter in your last issue, corroborating the statements of my article, "Bricks and Joints in Brickworks," in the "B. N." of the 14th. inst. He is, however, in error in believing that Fletton bricks, by the process of machine pressure, have all moisture taken out of them; this has to be done by the ordinary process of drying and firing. I quite agree with him with respect to "a good hard London stock," and from personal experience and observation, believe it to be almost imperishable—even in an atmosphere like that of London.—I am, &c.,

F. WALKER.

CHIPS.

A new Primitive Methodist chapel at Leybourne, near Louth, was opened last week. It was designed by Mr. John Thompson, and built by Messrs. Harrison Brothers, of Louth.

New Turkish baths at 461, Brixton-road, S.W., were opened last week. Mr. W. A. Large, of Chester-square, was the architect, and Mr. W. King, of Vauxhall Bridge-road, the contractor.

A new Roman Catholic church has just been commenced at Ilfracombe. It will consist of nave and apsidal chancel, 58ft. by 25ft., and will be built of blue Welsh stone, with Ham Hill stone dressings.

The new Home for Female Inebriates at 2, Millbank, West Derby, Liverpool, was formally opened on Friday by Mrs. W. E. Gladstone. The premises, which will accommodate 22 persons, were purchased, and have been altered to serve their new purpose. The work has been executed by Messrs. Eaton and Bulfield, Tuebrook, under the superintendence of the architects, Messrs. Cox and Marmon, Sweeting-street, Liverpool.

Messrs. Baird, Thompson, and Co. have introduced an installation of their latest improved combined automatic and mechanical system of ventilation into the Municipal Buildings of Oldham.

At a meeting of the committee in charge of the arrangements for the restoration of St. John's East Parish Church, Perth, held on Monday, it was stated that the cost of the alterations will amount to £1,450. It was recommended that the work be gone on with at once.

The London County Council discussed on Tuesday the recommendations of the Parliamentary Committee in respect to the construction of a new street from Holborn to the Strand. The scheme was approved several months ago, but certain additions were now proposed. Several of these points led to considerable discussion, but by narrow majorities all the recommendations were adopted.

Intercommunication.

QUESTIONS.

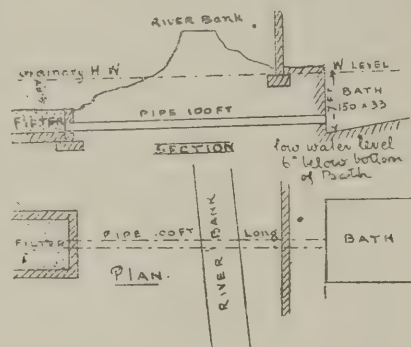

[10876].—**Cistern.**—I have lately seen a lead-lined rain-water cistern, which was lined with new 8lb. lead about six years ago, and which is now eaten away and perforated by small holes in a most extraordinary manner. The rainwater has been passed through copper gutters and pipes, and thence into this cistern. Will someone kindly inform me if the fact that the water has come into contact with the copper has anything to do with the speedy decay of the lead, and if so, an explanation will greatly oblige.—TEOTON.

[10877].—**Post-mortem Room.**—Can anyone inform me as to the following, viz.: 1. Best material for floor of post-mortem room? 2. Best material, size, shape, &c., for table? 3. Ought wall to have a Portland cement or white glazed tile dado, about 4ft. high and plaster above?—H. G. W.

REPLIES.

[10876].—**Boasting.**—If "One Who Wishes to Learn" will visit a stonemason's yard where freestone is prepared he would be shown a broad chisel about an inch wide, called a "boaster." Faces—and, in good work, beds and joints—are finished with this tool, and the work is specified "with boasted face, beds, and joints," as the case may be.—N. JOYCE.

[10852].—**Tidal River Bath.**—In reply to "N. B. D."

I inclose sketch as suggested, and thank him for his interest in the matter.—TIDAL WAVER.

[10875].—**Drainage of Dwelling-Houses.**—Owing to some error in transcribing or printing, the latter part of my question is stated incorrectly, and should read as follows: "It appears to me that the risk of unsealing the closet-trap by siphonage, evaporation by inconstant use, leakage through cracked earthenware, or other cause, is constant and great, and in such event the house becomes at once the exhaust for the drains."—P.

[10869].—**Tennis Courts.**—I should say cement on concrete would be better for the floor than gravel. Portland stone paving is often used. The best size for court is said to be 110ft. long, 40ft. wide, and 3ft. high. I presume I have understood the question aright.—G. H.

The opening of the new School of Applied Art at the Royal Institution, Edinburgh, took place on Friday night. Lord Kingsburgh presided. Dr. Rowand Anderson, director of the new school, gave an address, explaining its aims and objects, and the points whence it differed from existing art schools. Other speakers were Mr. Hippolyte J. Blanc, A.R.S.A., Mr. J. Birnie Rhind, and Mr. W. Wybrow Robertson.

A mission church and church institute is being erected at Kemblesworth, a rising colliery village, Durham, the foundation stone of which was laid on Monday week. The buildings are being erected in red facing bricks with stone dressings, in the Early English style, from designs by Mr. J. Gibson Cowe, architect, Fence Houses, at a cost of about £1,200, the contract for the whole of the work being let to Mr. Jennings, Chester-le-Street.

A new Roman Catholic Church at Bassalleg, near Newport, Mon., was opened last week. It is built of blue Pennant stone, with freestone dressings, and consists of nave, sanctuary, and organ chamber. There is a bell turret. Seating accommodation is furnished for 150 persons, and attached are the resident priest's house and a class-room. The architect was Mr. Gardner, of Newport, and the builder Mr. L. Hall, Maidee. The cost was £1,000.

At a meeting of the executive council of the Shakespeare Memorial Association, held on Friday, at Stratford-on-Avon, Mr. Algernon Graves informed the council that his late father, Mr. Henry Graves, the well-known print publisher, of Pall Mall, had, by his will, bequeathed ten valuable oil-paintings, all Shakespearian subjects, and 100 engravings, forming the Boydell Collection, to the Memorial Association, the pictures and engravings forming part of a loan collection now in the Memorial Gallery. Mr. Algernon Graves also presented as his own gift a painting of Mr. and Mrs. David Garrick, by Zoffany.

Legal.

STREET WORKS EXPENSES.

SO important is the Street Works Act, 1892, that it may be usefully referred to once more for the special purpose of directing attention to the clauses it contains as to the expenses of paving and making good new streets. Beyond the old power of recovering apportioned expenses summarily as before, section 13 now makes these expenses a charge upon the premises in a clear and unmistakable way with interest at the rate of 5 per cent. per annum. It further provides that the urban authority shall have all the same powers and remedies for the recovery of such sum and interest under the Conveyancing Act, 1881, and otherwise, as if they were mortgagees having powers of sale and lease, and of appointing a receiver. In order that an authentic record of these matters may be available, the clause goes on to provide that the urban authority shall keep a register of all charges under this Act, and of payments made thereunder, which is to be open for inspection by the public for a fee of one shilling in respect of each name or property searched for, while copies of the register are to be supplied on proper payment. This is, of course, the right way of doing the business, and when this is in order, any intending purchaser or mortgagee will be able to discover by a simple search whether or not the road, &c., has been paved and paid for, or whether any and what sum remains charged on the premises.

Section 15 gives the urban authority power to resolve to contribute the whole or a portion of the expenses of private street works out of the district fund. This clause apparently places it in the power of such boards to pay half, or some of the cost of paving, out of the rates; and there may be cases in which such a course of conduct might be desirable and advantageous in the public interest. By section 16 the urban authority is to have the apportioned expenses, which would otherwise fall upon churches, chapels, or other places of public worship, or the burial grounds attached, and which are to be exempted from such expenses where they are already exempt from poor rates. Again, in section 22 we have a new and special provision to the effect that no railway or canal company shall be deemed to be an owner or occupier for the purpose of this Act, which only abuts but does not communicate with streets that are chargeable with these private street expenses. This clause is guarded with provisions, and is not to apply to streets in existence on the adoption of the Act. But, all the same, it is a striking change in the law, as they have hitherto been liable for such improvement expenses; and though sometimes fair, it might often work out very hardly upon adjoining owners.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

LEGAL INTELLIGENCE.

SERIOUS CHARGE AGAINST A BUILDER.—At West London Police-court on Tuesday Frederick Banyard, a builder, was brought up on remand charged with the commission of certain offences under section 11 of the Debtors Act, 1882. In the early part of the year 1882 the prisoner was in partnership with a man named George Pearce. They traded as builders and contractors in the neighbourhood of Willesden, and it was alleged that a sum of £100 was obtained from a Mr. Memory, who had employed them to erect stables and other buildings, for the purpose of paying the workmen. The men were, however, not paid, and on the same day the furniture of both partners was removed. Subsequently proceedings in bankruptcy were taken, but no information was given by the debtors. Pearce was apprehended shortly afterwards, and was convicted. Banyard could not be found, and it was only recently, when he failed in another name, that he could be found. Mr. Grain asked the magistrate to commit the prisoner for the non-discovery of the £100, and the non-delivery of the furniture. He said there would be an indictment for conspiracy. The prisoner was committed for trial, bail being allowed.

IN RE C. R. GURR.—Charles Richard Gurr, builder, against whom a receiving order was granted on the 7th inst., states that in March, 1891, having then about £200 capital, he commenced the erection of

houses at St. Dunstan's-road, Fulham, but was eventually unable to carry them out. In or about December following the properties were realised, and, after payment of the advances, the net proceeds were applied in making payments to his unsecured creditors, in pursuance of a composition arrangement previously come to. He states that he was previously and has since been employed in his trade as a foreman bricklayer, taking sub-contracts. He attributes his insolvency to loss (£100 to £500) by the building speculation, and to loss in respect of a house at Shirland-road, Paddington. The statement of affairs discloses gross liabilities £1,060, of which £720 are unsecured, without available assets. The debtor makes no proposal, and has been adjudged bankrupt.

POOR CONCRETE.—At Lambeth Police-court on October 19th, Charles Watts, builder, Lower Kennington-lane, appeared in answer to five summonses, issued by Mr. Ellis Marsland, district surveyor for Camberwell, for having, in the construction of houses in Worlingham-road, East Dulwich, covered the site with other than a layer of good concrete at least 6in. in thickness. Mr. Biron, who had personally visited the houses, pointed out to the defendant that the material should be absolutely impervious to moisture. He ordered the defendant to pay a fine of 20s. and 2s. costs on the first summons, and a fine of 1s. and 2s. costs on each of the other summonses.

EXTRAORDINARY CHARGE AGAINST A LOCAL BOARD SURVEYOR.—On Tuesday week at the Southport Petty Sessions Mr. Thomas Lloyd, surveyor to the Southport Local Board, was charged at the instance of Mr. S. Zachery Lloyd, J.P., with stealing one load of clay, of the value of 1s., from Arelley Wood. When the case was called, complainant's solicitor said he wished to withdraw, as he now understood that the clay, which was the subject of the summons, was used for the purposes of the Local Board, and not for the private use of the defendant. His client had suffered great depredations by reason of persons taking sand and clay, and the bailiff, on information given, saw the defendant and asked him what he had been taking the clay for, and then he offered to pay for it. Investigations since made showed that the clay was needed for public purposes, and not for the private use of the defendant. He was instructed to ask that he should be allowed to withdraw the summons, and if necessary they would proceed against the defendant for trespass. Defendant's solicitor said the alleged robbery took place on September 20, and the summons was not taken out till September 30, so that ample time for consideration was given. His client had a complete and overwhelming answer to the charge, and if all the facts had come out before the Court, they would have felt the greatest indignation against the prosecutor. Case dismissed, with costs to defendants.

IN RE J. H. GARDEN.—At the Brighton County Court on Friday application was made for the discharge of a debtor, John Henry Gardner, of 5, Queen's-road, builder. His solicitor said the chief liabilities were incurred in connection with a brickfield, at Harrow, debtor having reason to believe he would be financed by a solicitor. Since the failure of the brickfield there were no debts which could be attributed to debtor's trading when knowing he was insolvent. Judge Martineau said he found continued trading to the end of 1889, when debtor was unquestionably insolvent; he found that books had not been kept, and that debts had been incurred while debtor had no reasonable expectation of paying them. There were liabilities of £3,297 and assets nil, and he did not think debtor should be allowed to go into business at once. The order would be one of five years' suspension, or for discharge forthwith on 10s. in the pound being paid.

EMPLOYERS' LIABILITY ACT.—On Thursday, Oct. 20, at the Clerkenwell County Court, before Judge Eddis and a jury, Willick Sallick, navy, sued E. O. Woodhead, builder and contractor, of 1, Alexandra-villas, Alexandra Park-road, for £240, compensation for injuries, under the Employers' Liability Act. The plaintiff claimed damages for injuries sustained by him by the falling of a wall on him at certain buildings in the course of being pulled down by the defendant, in Cromer-street, Grays' Inn-road, in January last. The wall fell on the plaintiff's legs, and since the accident he has been unable to follow his occupation. The jury found a verdict for the plaintiff for £180.

BAD MORTAR.—At Bromley Petty Sessions last week, George Pullen, builder, Penge, was summoned at the instance of the Beckenham Local Board for using mortar in building certain houses there which was not of the constituent parts prescribed by the local board's by-laws. Evidence was given to show that the mortar used by defendant contained under 4 per cent. of lime, the remainder being loamy fibrous matter, and entirely devoid of sharp sand. After the testimony of Mr. Carston, A.I.C.E., surveyor to the board, who took samples of the mortar while the premises were in course of construction, Dr. Adams, county analyst, said good

mortar was composed of one part of good lime to three of sharp sand as a minimum. None of the numerous samples taken from the defendant's building contained more than 10 per cent. of lime, and they broke off like snuff. Evidence was given to show that the mortar was good in the opinion of working bricklayers, but the Bench decided to inflict a penalty of £17 15s. 6d., including expenses, or 28 days. Defendant said he could not pay.

IS A GLASS HOUSE A BUILDING?—CORPORATION OF LEICESTER V. FRANK BROWN.—(Appeal Court, October 23, before Mr. Baron Pollock and Mr. Justice Hawkins).—This was an appeal by way of special case stated against a conviction for building a certain wooden building, with a glass front, beyond the front main wall of a house, without having obtained the written consent of the urban sanitary authority, as provided by the 156th section of the Public Health Act, 1875. Frank Brown, the appellant, was a photographer, and carried on his business in a house at the corner of the London-road and Coburg-street, Leicester. On April 26 this year he put up a structure 30ft. beyond the front of his house. This was a glass case, in which he placed photographs as an advertisement to his business, which was carried on in the house. The case was of wood, 9ft. 6in. long, 3ft. wide from back to front, and 7ft. high. It was roofed over, and had a glass front and a door to enter by at one end. The structure was fastened to the ground by four posts, forming part of the structure, and let into the ground to the depth of 9in. to 12in. The structure was large enough for a man to walk about inside. The house itself had no shop window on the side on which this structure was, and it served as such. The magistrates held that this structure was a building within section 3 of 51 and 52 Vict. chap. 32, and convicted the appellant. Mr. Rawlinson for Brown, cited a number of decisions in actions in which structures had not been held to be buildings—"Moore v. Williams," "Stevens v. Gourley," "Slaughter v. Mayor of Sunderland," "Brown v. Local Board of Holyhead." Mr. Toller, for the respondents, the corporation, argued that this structure came within the spirit of the Act, and relied on the case of "St. George's, Hanover-square v. Sparrow." Mr. Baron Pollock said that the conviction must be confirmed. No authority had been cited that in any way fettered the Court's discretion. In "Hibbert v. Acton Local Board" there was an expression of opinion that a conservatory was not a building, but that was on the construction of an Act which provided for the solidity of buildings which should be erected, and provided that they should be solidly built of brick or stone. Such a provision, if construed to apply to a conservatory, would make them useless, and prevent their being erected. The case in which a wooden movable pay-box was decided not to be a building was on the ground of its movable character and nature. In the present case the building was not movable, but its object was to assist in the carrying out of the business of a photographer. The object of the Act in using the words "house or building" seemed to contemplate such a structure, for it was to keep a free passage of light and air in the street. Everybody knew the sort of erections that were to be seen in urban districts, sometimes being cages for keeping animals or birds, and these might possibly not be buildings; but a structure of the dimensions of this one might be. It was not removable, being sunk into the ground. Mr. Justice Hawkins: If I were here to decide as a juror whether this was a building or not, I might come to a different conclusion; but, as the law says, if there is a difference of opinion as to whether it is a building the magistrates are to decide, and as they have exercised a reasonable discretion, and come to a reasonable conclusion, I do not think it ought to be interfered with. It is difficult to draw a line, and each case must depend on its own circumstances as to what is a building.

New blocks of constabulary barracks are being erected facing the municipal building at Bradford. They will accommodate upwards of 100 men, and are provided with recreation rooms and baths, as well as the necessary dormitories and drill courts. The buildings are of plain brickwork, with no ornamentation.

The other day the directors of the North-Eastern Railway Company, accompanied by their engineer, Mr. Harrison, had a thorough inspection of the new line of railway now being constructed from Annfield Plain to a junction of the Team Valley line between Chester-le-Street and Birtley. Messrs. Whittaker, contractors, of Leeds, have the work in hand, and the railway, when completed next year, will provide travelling facilities to what has hitherto been a part of Durham County rather difficult of access. The lines, which are to be double, will be seven and a half miles long, and will pass Annfield Plain, Shield Row, Beamish, and Pelton, with stations at each of these places, to the Team Valley Junction.

STATUES, MEMORIALS, &c.

DURHAM.—The altar-tomb erected as a cenotaph memorial to the late Dr. Lightfoot, was unveiled in the choir of the cathedral on Thursday in last week. The monument, which is in the style of the fifteenth century, is composed of alabaster, with moulded base, string, and cornice of a dark-grey marble. It contains panels of alabaster, three in each side, and one at each end, all filled with moulded and cusped quatrefoils bearing shields charged with the arms of the diocese of Durham, Lightfoot, and Durham and Lightfoot impaled. The marble cornice has, in brass let into it, an inscription in Latin from the pen of the Bishop of the Diocese. Above the cornice is laid the effigy, in white marble, of the late Bishop, who is represented in the episcopal robes, the hands folded over the breast, the feet resting against three books. The model for the effigy was made by the late Sir Edgar Boehm, Bart., and was nearly finished at the time of his sudden death, after which the work was taken up and completed by Mr. Alfred Gilbert, A.R.A. The altar-tomb has been made by Messrs. Farmer and Brindley, of London, from the design of the Cathedral architect, Mr. C. Hodgson Fowler, F.S.A., M.A.

OXFORD.—A chamber is in course of construction at University College, Oxford, for the reception of the Shelley Memorial, presented by Lady Shelley. A cast of the monument itself was exhibited in the Royal Academy this year. It is the work of Mr. Onslow Ford, A.R.A. The chamber, which is designed by Mr. Basil Champneys, the architect, is being made in that part of the college that lies between the old buildings and what are called the new, behind a long piece of wall on the High-street. The chamber will not be visible from the street, as it will be sunk below the level of the ground. It will be lighted at one end from a glass cupola, beneath which the monument will rest. At the other end will be a platform for the spectators. Mr. Ford's work consists of a figure in white marble of the poet as he may be supposed to have lain when washed up by the sea. It is on a bronze pedestal, supported by lions, between which a muse is seated.

CHIPS.

The dissolution of partnership is announced between E. Richards and F. P. Harrison, under the style of Richards and Harrison, of Torquay, architects.

The well-known Tolbooth Free Church, Edinburgh, has been sold to the Scottish banks for a "clearing-house," for the sum of £14,000.

The Bishop of Chichester laid, on Friday, the foundation-stone of a tower and ante-chapel at St. John's College, Hurstpierpoint, one of the schools of Canon Woodard's foundation. A sermon was preached by the Bishop of Southwell.

The new public park at Colchester was opened on Monday by the Lord Mayor of London. The park comprises the ground round the Castle, together with the contiguous meadows which lead down to the river, the entire area being about 17 acres.

The redecoration and cleansing of the roof of the City Guildhall has just been completed. The work has been carried out by Messrs. Mowlem, under the direction of Mr. A. Murray, the city surveyor.

The new municipal buildings at Saltecoats, N.B., erected at a cost of £4,000, was opened on Friday.

At the restoration of St. John's Church, Milbourne Port, near Sherborne, in 1867, under Mr. Henry Hall, of Doughty-street, W.C., the Ham Hill stone capitals to the arcades and the blocks supporting the external pinnacles were left uncarved. Funds have recently been raised for the completion of the work, which has been carried out from Mr. Hall's designs by Messrs. Harry Hems and Son, of Exeter.

The magistrate at the Wandsworth Police-court on Wednesday week imposed fines amounting in the aggregate to £21 14s. upon an owner of cottages in White-square, Clapham, for neglecting to put his property in a sanitary condition. The defendant had rendered himself liable to penalties of £420.

At Tuesday's meeting of the General Purposes Committee of the Bangor City Council the plans of a new pier it is proposed to construct at Garth were submitted by Messrs. Mayo, Manchester.

The new flagstaff which is to bear the Royal Standard at Windsor Castle was successfully stepped on Saturday afternoon. Four Maundy coins obtained from the Mint were deposited under the butt before it was lowered into position. Five days were occupied in the preparations and in the lifting of the flagstaff to its elevated position on the Round Tower, the work, which was difficult and trying, having been superintended by the Castle master gunner. The pole is 72ft. in height, and is of Oregon pine.

The Society of Merchant Venturers have voted £1,000 as their contribution to the restoration of Bristol Cathedral.

WATER SUPPLY AND SANITARY MATTERS.

ABERDEEN.—The town council of Aberdeen have adopted a report by Mr. Gale, C.E., for improving the supply of water to the city. Under the scheme filters will be constructed at Invercarnie at an estimated cost of £30,000; a settling pond, £20,000; distributing mains £17,000; and service reservoir at Kittybrewster, £5,000—the total estimated outlay being £72,000. The works will be carried out under the direction of Mr. Dyack, burgh surveyor. It was resolved that a Bill should be promoted in the ensuing session of Parliament seeking power (1) to compel the County Council of Aberdeenshire to treat by irrigation the sewage of all the villages along the course of the Dee, and (2) to provide proper filter beds and settling ponds for the whole supply of the city. The committee further resolved to institute a thorough investigation as to the present excessive waste of water and the means for its prevention, since in this way a considerable saving of expenditure could be effected.

BALMORAL AND RIVER POLLUTION.—It should at once be said that Balmoral has fared somewhat unfortunately in connection with the question of the pollution of the Dee. It was the only mansion house against which complaint was made when others were offending quite as badly, and it is the only place, mansion house, or village where anything has really been done to remedy or mitigate the evil. It was not denied that pollution existed at Balmoral. But when complaint was made, Dr. Profeit, Her Majesty's Commissioner, had a report drawn up by a resident engineer, and by an eminent consulting engineer, Professor Ivion Macadam, of Edinburgh, and at once set afoot "the best practicable and available means to render harmless the sewage matter." A considerable sum has been spent in these operations, and it is only fair to say that there is no doubt whatever that a Rivers Pollution Commissioner would pass the new arrangements as sufficient to meet the requirements of the Act.

HAUXLEY AND TOGSTON WATER SUPPLY.—The new waterworks for the townships of Hauxley and Togston, in the Alnwick Union, have just been completed for the rural sanitary authority. A new settle-well and 25,000-gallon covered service reservoir has been built near the 21-gallon spring, and over eight miles of 4in. and 3in. cast-iron socket pipes have been laid down to supply a population of 1,600. The main was laid across the River Coquet, at the paved ford near Warkworth Mill, when the water was only a few inches deep at the time. The first four pipes were jointed together and then laid in the river with one loose end on the land and the socket end supported just above the water, and then the fifth pipe was jointed on and then let into the water, leaving the end out ready for the sixth pipe. This process was repeated with each pipe, the men working in the water, until the river was crossed with 24 pipes in all. The open end on the north bank was then connected to the main with a loose collar, and on the southern bank the pipe laying proceeded in the usual manner. The works have been executed by Mr. John Carrick, of Durham, from plans prepared by Mr. M. Temple Wilson, of Alnwick, Northumberland. Mr. J. A. Huston, of Caton, was clerk of the works.

OLDHAM.—Mr. Arnold Taylor, C.E., an inspector under the Local Government Board, held an inquiry at the Town Hall, Oldham, on Friday, into an application made to them by the corporation for leave to borrow £200,000, to be expended on sewerage works. The works proposed to be constructed comprise a system of sewers passing around the boundaries of Oldham, with the object of intercepting the existing sewers, and conveying the sewage thus intercepted to a site adjoining the site of the sewage works of the Chadderton Local Board, where it will be dealt with by filtration. This scheme has been prepared by Mr. Law, C.E., of London. Practically no opposition was raised at the inquiry to the works proposed, or to the borrowing of the money by the corporation.

A discovery of Roman remains has just been made at Westernmain Sandpit, near Kirkintilloch, about 7 yards behind the line of the Roman wall. The finds include a cist of sandstone, a vase of reddish clay, a spearhead, and some human bones.

The employes of David Davies, builder, of Cardiff, who are now engaged in the erection of the new town hall and market hall for Tredegar, died together at the Tredegar Arms Hotel on Friday night. Among those who responded to toasts were Mr. Davies and the clerk of works, Mr. Edward Morgan.

Sir George Humphry, Professor of Surgery at Cambridge University, has presented to his native town of Sudbury, Suffolk, a portrait of himself and a portrait of Mr. G. W. Andrewes, who has been an alderman of the borough from the passing of the Municipal Corporations Acts in 1835, and was its mayor both in the year of the Queen's accession and of her Jubilee.

Our Office Table.

MR. ASTON WEBB, the hon. secretary of the R.I.B.A., has resigned in consequence of his inability to attend to the duties of the office, owing to the great pressure of his professional work. The council have nominated Mr. William Emerson, a member of the council, to the vacant office, and the election, which is little likely to be contested, will be announced on November 21. A more popular or able hon. secretary than Mr. Aston Webb has never held office, and Mr. Emerson will in every way make a worthy successor to the post.

ANOTHER step has been taken this week towards the acquirement for the people of the Albert Palace at Battersea. It will be remembered that this handsome building, which cost for erection £150,000, and is only separated by a roadway from Battersea Park, was recently offered for sale at £20,000. While the local authorities were hesitating as to whether the ratepayers would endorse their action if they purchased, an anonymous donor offered to buy the palace if the Battersea Vestry and the London County Council would undertake its maintenance. The Battersea Vestry held a special meeting on Wednesday evening to consider the question, and by a large majority decided to vote their quota. The London County Council can now scarcely decline to do the rest, and we should hope the acquisition of the Palace for the benefit of the public may now be regarded as a settled fact.

It is expected that the work of removing Alfred Stevens's monument to the Duke of Wellington, from the Consistory Chapel at St. Paul's to a space beneath the easternmost arch on the north side of the nave of that cathedral, will be completed early in 1893. The work of reconstruction will be begun in about a fortnight's time. The work of removal has been carried out under the direction of Mr. Penrose, Surveyor of the Fabric. Mr. George Shaw, who has acted as mason, has had the invaluable aid of Mr. F. Doughty, who worked with Alfred Stevens for five and a half years, and who practically put up the monument. The bronzes have been removed by Mr. Young, the founder who cast them. From an anonymous friend, Sir Frederic Leighton has received a cheque for £300, the sum needed to complete the amount necessary for the removal of the monument.

We regret to learn that the Legislative Council of Victoria has rejected the Architects' Registration Bill promoted by the Royal Victorian Institute of Architects on its second reading. Nominally the opposition was promoted on the ground that the measure would create another close profession or trades-union, the present majority of the Council priding itself on being the special guardian of freedom of contract; but the discussion revealed that the real opponents of the Bill were the Builders' and Contractors' Association, who feared that such a law would militate against their interests. Some architects also thought the Bill too stringent, and objections were raised in the course of the discussion to clauses 39 and 43, one of which provided that after six months from the appointment of the Registration Council, no person not registered as an architect should be able to recover any charge for professional services, while the other stipulated that after the same period no expert evidence should be given in courts of law, unless by special consent, except by registered architects. The feeling against professionalism seems to be general just now in the Victorian Legislative Council, for only a few weeks ago the Medical Bill was rejected on similar grounds. We are informed by correspondents in Melbourne that the present government is by no means firmly established, and next session an amended Architects' Registration Bill will be introduced under more favourable auspices.

SIR JOHN B. MONKTON, town clerk of the City of London, in presenting the prizes and certificates granted by the Worshipful Company of Plumbers, London, to the students in the plumbers' classes at the Durham College of Science, Newcastle, said he knew and appreciated a piece of good plumbing, for a piece of bad plumbing was a very insanitary and a very bad thing. Of all craftsmen, he supposed the plumber was the man who worked most in the dark. He burrowed behind walls and under

ground, and was, in fact, so to speak, always out of sight. There was, perhaps, no trade which afforded such opportunities for "scamping work," and there was no craft the work of which, if scamped or badly executed, was so utterly dangerous to humanity. Therefore, he thought it was fair to draw the logical conclusion that there were few crafts which were more important to the well-being of the public if properly carried out than the plumber's craft. Men who were conscientious in that work could therefore feel that their good work was appreciated.

MEETINGS FOR THE ENSUING WEEK.

FRIDAY.—Architectural Association. "Notes on the Application of an Architectural Education," by William Young. 7.30 p.m.

The Architectural Association, 9, Conduit Street, W.; and 58, Great Marlborough Street, W.

THE ARCHITECTURAL ASSOCIATION COURSES OF LECTURES, CLASSES, and STUDIO INSTRUCTION are now commencing.

The Courses are both Elementary and Advanced, and are designed to provide a sound professional education, supplementary to that to be obtained by the prevailing system of pupillage. The Course, which is in four divisions, is progressive and consecutive, and the instruction is given by Lecturers and Instructors of known ability.

DIVISION I.

LECTURES and CLASSES.—The Orders of Greek and Roman Architecture, Building Materials, Perspective, Physics.

THE STUDIO.—Drawing from Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Plane Geometry, Criticism Meetings.

DIVISION II.

LECTURES and CLASSES.—English Architecture, Materials, Elementary Ornament and Colour Decoration, Strength of Materials, Stresses and Strains.

THE STUDIO.—Designs based upon Ancient Examples, Freehand Drawing, Drawings of Examples of Elementary Construction, Solid Geometry, Criticism Meetings.

DIVISION III.

LECTURES and CLASSES.—The History of Architecture, Materials, Colour Decoration, Sanitary Science as applied to Drainage and Water Supply.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Perspective and Sciography, Constructive Masonry, Criticism Meetings.

DIVISION IV.

LECTURES and CLASSES.—The History of Architecture: Sanitary Science—including Ventilation, Lighting and Heating, Painting, Sculpture; other Arts allied to Architecture; Professional Practice—including Legislative Enactments relating to Building Contracts.

THE STUDIO.—The Design and Construction of Modern Buildings, Freehand Drawing from Casts, Drawings of Ancient Buildings from actual measurement, Graphic Statics and Perspective, Criticism Meetings.

EXTRA SUBJECTS.

LECTURES and CLASSES.—Plane and Solid Geometry, Geology, Mensuration, Land Surveying and Levelling, Chemistry of Building Materials, Quantity Surveying—including the Preparation of Estimates, Discussion Section.

THE STUDIO.—Sketching and Measuring, Elementary Water Colour Class, Water Colour Class, Modelling.

A Pamphlet, containing full particulars of the curriculum, may be obtained free on application to the Hon. Secs., at 58, Great Marlborough-street, London, W. Fees must be paid in advance, and passes may be obtained at the Offices of the Association, between Ten a.m. and Seven p.m.

ERNEST S. GALE, } Hon. Secs.
F. T. W. GOLDSMITH, }

CHIPS.

The dissolution of partnership is announced as between A. G. Lavender and J. Wells, of Glasshouse-street, Piccadilly-circus, architects and surveyors.

The Glasgow Police Commissioners decided on Monday to erect baths and washhouses for Springburn district on a site in Wellfield-street, at an estimated cost of £11,000.

The local board of Smethwick have approved of plans prepared by Messrs. Harris and Harris, of Birmingham, for the completion of the sewage of West Smethwick. The present works will involve a further cost of £5,000, bringing the total outlay to about £20,000.

New offices are being built at Blackburn for the proprietors of the *Northern Daily Telegraph*. The premises occupy a corner site, and are faced with red bricks, with buff terracotta dressings, while the roofs are covered with green slates. Messrs. Stones and Gladwell, of Blackburn, are the architects, and Messrs. Highton and Son, of the same town, are the contractors. The outlay on building and machinery will exceed £20,000.

The death occurred at Padstow, last week, of Mr. James Vivian, retired builder of that town. Deceased, who was in his 80th year, had taken an active part in all public movements in the town, and for about 60 years had been a worker among the local Wesleyans. He was vice-chairman of the Padstow Local Board, and had also served on the local school board.

The Town Council of Birkenhead have confirmed the arrangement made with Mr. T. C. Thorburn, the borough surveyor, who has retired, that he shall be appointed consulting surveyor at a salary of £250 a year. They have decided to offer candidates for the vacant office a commencing salary of £500 clear of all office expenses, but with no claim for superannuation or pension in the future.

RESTORED BY MR. JOSEPH MÖCKER ARCHT.

THE BUILDING NEWS

AND ENGINEERING JOURNAL.

VOL. LXIII.—No. 1974.

FRIDAY, NOVEMBER 4, 1892.

THE LONDON COUNTY COUNCIL AS BUILDERS.

ON the 18th of last month, as we reported in our issue of the 21st ult., the London County Council resolved to become their own builders for the erection of artisans' dwellings for housing the persons displaced by the formation of the approaches to the Blackwall Tunnel. What, the question naturally arises, has driven the Council to determine upon this course? Is it a question of economy?—or is it that the Council have found difficulties in obtaining tenders from contractors, since they have imposed certain clauses in their contracts referring to rates of wages, hours of work, and trades unions? We are inclined to think there is more in this than at first meets the eye. The contractors do not like the terms of contract; so the Council say, "then leave them alone, and we will be our own contractors."

The step which the governing municipal body of London has taken is one of the gravest importance, and whether or not the difficulty of obtaining tenders has been the immediate cause of bringing this question to a climax, certain it is that the "labour" party of the Council have cried out for the "municipal workshop" ever since the formation of the Council. We cannot pretend to determine whether the Council, by entering into building operations, is going beyond its duties as an administrative body, as pointed out by one of its members, but one thing is certain, that the internal administration of the Council will have to be very considerably altered to meet the demands of the working of a "building department" which must arise if the work of the Council is to be carried out with that efficiency and perfection which some of its members contend can alone be acquired by abolishing the contractor.

The only department of the Council that can at all cope with this additional work (which is to be thrust upon the shoulders of the officials, without much consideration of its magnitude) is the architect's department. Now, are the Council about to request their architect to become their master builder? or are the Council going to create a new department for the carrying on of this work? Whatever is done in the present instance, if the Council become permanently their own builders, then they must have a building department apart from the architect's department.

When we consider that the works under the control of this body already include such vast undertakings as the bridges, tunnels, sewers, ferry boats, artisans' dwellings, street improvements, lunatic asylums, &c., it will be seen that the Council will become the employers of large armies of labourers and artisans for the execution of the work which has heretofore been performed by contract. The actual building work is small compared with the engineering works that must be executed by them, and the same questions arise in connection with this department as with the architect's. The policy of this municipal body in passing its resolution to build itself has been severely challenged in the daily press. One writer to the *Standard* complains that the Council will not be able to find any officer competent to take the place of the contractor, and take such means and make use of such checks as will prevent the attempts at speculation and robbery that"—states this writer—"are ways made in connection with the expendi-

ture of large sums of money on works." "However honest," he goes on, "or conscientious agents may be, they are not so keenly alive to the interests of their employers as a contractor is to his own interest, and, besides, a contractor is always much more on the look-out for delinquencies of the character above described than any agent can be. Then, all agents are not honest, steady, and reliable, and a contractor has to keep a close watch upon these men to see that they do their duty. What individual can the County Council find who can possibly pay the same attention to all these matters that a contractor does whose personal fortune is at stake? I venture to say that this *rara avis in terris* cannot be found, because he does not, in fact, exist. Everyone who has had actual experience in the carrying out of works knows that when a workman is in the employ of a company or a public body for day's wages he will not do nearly as much work as he will do for an individual."

This unwarranted and wholesale condemnation of the officers of public bodies did not go unanswered, for one signing himself "An Officer of the Council" entirely refuted these statements, and pointed out that "such *rara aves* not only exist, but are plentiful, and the Council have such at present on their staff, and one at least I know who has already been honoured by their confidence to carry out the erection of a small building in the vicinity of London, and although his 'personal fortune' is not at stake, he is sufficiently honest to look after the work as if it were."

We cannot say how far the Council are right in taking this step. We are, however, fully cognisant of the vast magnitude of the question, and fear the individual members of the Council have not all grasped the details of the proposed reformation in the execution of their public works. There is great truth in what Sir John Lubbock said in warning to the Council that "a municipality or a government might control everything, but it could not undertake to do everything." Is the Council undertaking too much? Is its present strength sufficient for the extra pressure on the actual working "members" of the body—i.e., the officers?

The scheme cannot work without the creation of a building department. It is not necessary to tell our readers the vast amount of routine and work that has to be gone through in the contractor's office and workshops and builder's yard; but it is necessary to remind the Council that, to carry out their own building operations, they will have to do as much work in their offices as the contractors have to do in theirs. Others than bricklayers, carpenters, and masons will have to be paid, and the Council were reminded by one of their own members that if they wanted their work well done they must have skilled superintendents, and not attempt to "sweat" their brain-work.

We await the result of the experiment of the Blackwall Artisans' Dwellings with interest, and wonder whether the ratepayers will be informed of the prices given in the tenders that were rejected, and the actual sum spent in the erection and superintendence of the buildings. We are inclined to think that it will prove that Sir John Lubbock was right in saying that "government and municipal work was always more expensive than private work."

There is another and perhaps more important side of this question, than that of administration—namely, that of the employment of labour, and the creation of public works for the occupation of the unemployed. This is a social question of such depth, involving many serious arguments, that beyond reminding our readers that the resolution of the council we are now dealing with tends towards the employment of municipal labour in London, we do not propose to deal further with it here.

THE SOUTHWARK BATHS AND WASHHOUSES COMPETITION.

THE Southwark Commissioners of Baths and Washhouses have selected three out of the 15 sets of designs submitted for the proposed new baths to be erected at the corner of Lavington-street and Ewer-street. The plans of Mr. F. J. Smith receive the first premium. The author exhibits a practical knowledge of the requirements. A commodious and well-planned entrance in the centre of the Lavington-street frontage is shown for the men and women, with separate lobbies and waiting-rooms. The pay-box is central between the two entrances. On the left side are the second-class women's private baths, ten in number, and on the right hand, or Ewer-street corner, the first-class men's private baths for twelve, arranged in three rows. These private baths form lateral wings to the entrance block, and a straight wall in the rear cuts the whole of this front block off from the two swimming-baths, which run parallel to Ewer-street. The first-class for men, 100ft. by 30ft., is the largest, and occupies the left-hand side of the site, with rows of 57 dressing-boxes 4ft. by 3ft. 3in. each, and with a 4ft. platform in front. The entrance is from the vestibule, and an official corridor for access to the laundries, &c., runs from end to end, dividing this swimming-bath from the adjoining second-class one, which is 75ft. long and 30ft. wide and has 49 boxes, and abuts on Ewer-street. This general arrangement of two parallel swimming-baths is necessitated by the oblong shape of the ground, the longest side of which faces Ewer-street. The entrances to baths, main stairs to gallery, and other conveniences are well planned for classification. The drying-houses, washhouse, and laundry are at the end of the second-class swimming-bath. The author has designed his main baths as separately roofed buildings. An open timber roof, with skylight, is shown over the men's bath, and a timber and iron-trussed roof over the second-class swimming-bath, the official corridor between them being roofed low and top-lighted. The basement plan shows the spaces between the swimming-baths and under the boxes utilised as tunnels for the piping. The first floor has a gallery round three sides of the first-class swimming-bath, and in the front block over the private baths are the five first-class women's baths, and in the right-hand wing are 24 second-class men's, top-lighted, each division with its own stair, with the artists, superintendent's, and commissioners' rooms in the centre. A gymnasium is provided for in connection with the second-class swimming-bath, while the second floor, confined to the centre block of main front, is devoted to the superintendent's residence. The elevation towards Lavington-street is arranged with a centre three-story block, having a high roof and side wings. There is a wide centre elliptical archway, and the general features and details are Italian.

The second premiated design is by Messrs. Geo. Elkington and Son. In this, the main swimming-baths are similarly disposed, with a central corridor between, not carried higher than the ground story. The first-class bath is 107ft. by 46ft., having 59 dressing-boxes, with a water surface of 100ft. by 30ft. The second class, on the Ewer-street side, is 82ft. by 45ft., with 48 boxes, and a water area of 75ft. by 30ft. The front block has two rather narrow centre entrances leading to the respective waiting-rooms for each sex, though there are two other end entrances provided, one for the women, and the other for the commissioners at the Ewer-street corner. The women's second-class private baths on the left side provide for ten, and are conveniently arranged and lighted. On the other side of entrance is the commissioners' room and office. Washhouses 29ft. by 42ft., with 24 compartments, are behind the second-class swimming-bath. A

gallery is shown round the first-class bath, and 12 men's first-class and 24 men's second-class private baths are arranged in the front block of first floor. The second floor has only the superintendent's private rooms. A timber-framed roof is shown over the first-class swimming-bath, and a timber roof, with iron ties, over the second; both have raised skylights. The authors have provided for meetings and entertainments by arranging the gymnasium in the second-class swimming-bath, and covering over the area of the first-class bath as a public hall. The elevations are in red brick with stone dressings, a rather too ornamental Renaissance style being adopted with corner towers over entrance, and with open parapets and other details. The flank elevation to Ewer-street is not agreeably balanced, as it shows a long flank to the bath with two-storied end buildings.

The third design, by Messrs. Spalding and Cross, has certainly the best elevation of the three, designed in a free 18th-century style of Classic, with rusticated stone basement supporting a red brick and stone superstructure. Ionic pilasters adorn the centre portion of the façade, which is surrounded by a turret of pleasing outline rising from a tile roof, and the side wings are accentuated at the extreme ends by pediments. The plan has a well-arranged and spacious centre entrance, with lobbies for men and women, and a ticket-office between them. A spacious hall, with first and second-class waiting-rooms, giving access to their respective swimming-baths, and to the women's and men's private baths on the left and right, forms a good feature; but we do not like the arrangement of the two classes on the women's side, a separate front entrance to which is provided; nor do we think the continuation of the men's second-class private baths round Ewer-street along the outside of second-class swimming-bath is desirable. The first-class men's private baths are in front on the right hand of main entrance. The two swimming-baths are placed side by side; the first-class is 100ft. by 30ft., and the second-class bath 75ft. by 30ft., these being the dimensions of the water surfaces. The authors' cross-section represents an arched ribbed timber roof, with raised lantern over the former, and a semicircular open ornamental iron truss over the latter. There is a gallery to the first-class bath, and the total height from water surface to roof is 35ft.

By the introduction of iron columns supporting the circular iron trusses of the second-class bath, the author obtains a girls' gymnasium, 85ft. by 6ft., over the side dressing-boxes, and a boys' gymnasium, 74ft. by 15ft., is provided on the other side by the erection of a second story over the men's private baths facing Ewer-street. There are subways under the dressing-boxes for pipes.

Viewing the relative merits of the designs, the third premiated set has many qualifications which entitle it to rank high, and it takes the lead as an architectural design. The strength of the first premiated design is in its plan; the author raises his ground-floor level above that of the street, and thereby gets a fall for emptying the bath; provision is made for meetings and entertainments by movable floors over the bath, and the author has also seen the need in view of such accommodation of a large vestibule space, and for means of obtaining an additional exit. The engineering details are well considered also; all exhaust steam is utilised. The cost is estimated at £19,850, exclusive of gymnasium.

ROYAL SOCIETY OF BRITISH ARTISTS.

THIS exhibition, if not equal to some of the former displays, maintains a fair average. The fine landscape of Adam E.

Proctor, a young member (4), is tenderly painted—a riverside scene, the water filling the foreground of the canvas, with floating lilies and a margin of rushes; beyond them is a group of willows, between the branches of which is a sunlit meadow; the light and shadow and reflection, and the freshness of the foliage, are painted with much beauty. R. W. A. Rouse also gives several of his vigorous landscape effects; the stormy sky and the effect of sunshine on the hilly range (15) give a good idea of the atmospheric conditions conveyed. Another, "The Coming Storm" (130), and a few in the other galleries, will be noticed for their characteristic freshness and strength of handling. Edgar Bundy, a young and rising painter, sends one of the best pictures. "To We Three" (30) is an interior of a room in an old hostelry, with furniture and fittings of the 17th century, where two gallants in the costume of the period are sitting drinking to the health of a comely lass who stands on the opposite side of the table. The girl's figure, in a darkened room, is thrown into strong relief by the light coming through an open mullioned window, through which a sunlit garden is seen. The movement of figures, drawing, grouping, and colour are admirable, and the accessories carefully drawn. Some small but clever figure-subjects are hung round the fireplace, Haynes King's figure of a housemaid in an armchair (51) and H. G. Glindoni's card group (52) being amongst the best. Arnold Priestman (59) has a broadly-painted landscape, very clever in its stormy atmosphere, "Wind-blown." Frank Brangwyn's "Pilots, Puerta de Passages" (68) is a dexterous study of dark figures on a verandah against a strong, sunlit background of houses; and A. Glendenning's "Adversity" (65) is remarkable for its pathetic rendering of a man and wife on the outskirts of a town. The grey, showery atmosphere, and the light and reflection on the wet ground, is painted with much fidelity. G. C. Haite has a clever sketch of a Dutch Market (64); J. L. Pickering a pleasing autumn landscape. John R. Reid is represented by a forcibly and poetically painted coast study, "The Storm"; while for large canvases, "Suspense" by W. H. Pike (138), and "In Sight at Last," by W. Peter Watson, call for attention. The first represents a cottage interior, where a labourer, with two little girls, sit round a fire, a flickering candle by the window, through which the cold grey light of early dawn appears, telling of a long night of watchfulness and anxiety, probably the dangerous illness of a wife and mother. The last-named picture is also a pathetic incident: a seated old woman, an invalid mother propped up by pillows with her daughter, scanning the sea before her humble cottage for a loved husband or son, whose vessel is in sight. The President's (Mr. Wyke Bayliss) "Votive Chapel" interior, "For those at Sea" (131), is full of poetry, light, and colour; and another picture, "A Golden Spring" (172), by W. Gilbert Foster, is of merit. In the South-East and South-West Galleries we notice two or three talented interiors by John A. Lomax, "Down on His Luck" (367), "Forbidden Lore," a girl perched on a library step-ladder reading (207), and "Dry Reading" (232); a large view of "Durham," by Albert Stevens, enveloped in smoke and mist; a capital ideal head study, "Clematis" (208), by G. Sheridan Knowles; figure-subjects by L. C. Henley in his accustomed sentimental style. John R. Reid's "Fisherman's Bairs" is certainly one of his best works; H. Harwood's "Cornfield" (233) is excellent in tone and handling.

The water-colours are strong. Albert Kinsley (381) "Autumn's Sweet Decay" is delicate and sweet in tone, and his other works in the same key of landscape are worthy of his pencil. Leopold Rivers (385),

R. B. Nisbet (389), T. B. Hardy (390), and G. C. Haite contributes some characteristic landscape studies. Ernest George's pair of drawings, "San Lorenzo, Genoa" (412) and "Albenga" (419), are clever and bright sketches of towers in strong sunlight. W. Harding Smith sends a careful drawing of "Crypt, Church of S. Leno Maggiore, Verona" (473); but the great attraction in the North-East Gallery is the inimitable screen of sketches of Continental cathedrals by the President, Wyke Bayliss. These are delightful studies in water-colours—first notes of light and shade, which is ever changing, and from which the methods of work of this consummate painter of ecclesiastical interiors in their sublimest moments of gleaming light and gloom may be seen. Some of these sketches, as those of "The Certosa di Pavia" and "San Miniato, Florence," are slight pencillings with thin washes of colour. Seventeen sketches, including two beautifully finished drawings of Evreux and Antwerp Cathedrals are, hung. In the North-West Gallery the "Interior of Coutances" (392), taken from the ambulatory round the apse, is a marvellous example of perspective, colour, light, and shadow, and the power of the painter in producing a perfect melody.

INSTITUTE OF PAINTERS IN OIL-COLOURS.

IN the three galleries in Piccadilly, containing over 600 pictures, the most uncritical amateur and buyer may find plenty to admire. A necessarily large number of works of a mediocre quality are to be seen among so large a collection, and we can do no more than glance at each gallery. The West Gallery contains about a dozen works of merit. Perhaps J. C. Dollman's "Dead or Alive" will find more admirers than Edgar Bundy's work further on, or even than Sir James D. Linton's "Approaching Michaelmas" (143), but each is excellent in its way. Mr. Dollman again gives us a bit of his rare pleasantry in the stalwart highwayman who, pistol in hand, his dying horse lying at his feet by the roadside, possibly over-worked, is prepared for his pursuers, who are seen in the distance. With one pistol in readiness to fire, and another in his breast-pocket, there is little chance of escape for one or more of the half-timid officers. The landscape and distance, with the winding road through a bleak common, are capably drawn in the perspective; the horse with the saddle, back to the spectator, is masterly. "His Worship's Dinner," by Edgar Bundy, is also full of life and powerful drawing and colour. On the large wooden table the cook is holding up the neck of a large swan, one of the items which is being read out by the steward. On one side is a deer, and there are fish, and poultry, and fruit—quite Snyder-like in the prolific luxuriousness of the wealthy man's table; but the work is less pleasing than Mr. Bundy's admirable picture in another gallery, "To We Three." The President's work, "Approaching Michaelmas" (143), is a charming cottage study, with sunlight glinting over its front, its thatched roof backed by dark trees, and the foreground clothed with foliage and flowers. On the top of the rustic steps sits a girl, watching some geese in the fore part of the picture. The whole is full of tenderness and pathetic interest. C. Burton Barber's "Under a Spell" is also a clever study of a young girl seated by a table fondly stroking with her quill pen a little dog on a chair, and soothing it to sleep. Other pictures of this class which call for notice are the Hon. Duff Tolle-mache's "Le Curieux" (12), an old collector, in his shirt sleeves, examining a watch; Hugh Carter's "Rest by the Way," a girl resting her basket on a steep cliff by the sea; Arthur Meade's "Attentive Audience," J.

Watson Nicol's "Love's Labour Lost," a boy playing a whistle-pipe to a caged magpie; Davidson Knowles' contemplative but rather motiveless picture of young lady on a stile in a woodland, "The First Time of Asking" (44). Landscapes and seascapes which are strong may be instanced in the following pictures:—F. W. Baker's "Toilers of the Sea" (2), a well-painted seascape, with boats within a rock-built harbour; Robert W. Allan's fresh study of the sea, "The Breezy Blue" (13). Claude Hayes gives us some very natural colour and sentiment in his "Surrey Common," with the caravan and gipsy life. Edmund G. Waller's fine landscape representing the effects of "Sunshine and Shade" (60) is a peep of a sunny distance through dark, overhanging trees. Richard Wane paints a group of red-tiled cottages under a cliff skirting a bay with its blue sea in "Burnmouth, Berwick-on-Tweed"—quite strong in colour. E. M. Wimperis, in "A Sussex Lane," gives us one of his broad, hazy landscapes, lit up by gleams of the sun, admirable in its strength of colour and bold handling of trees and foreground. "The Fallow Plough," by H. Hughes Stanton, looks rather hard and lacking in atmosphere, though clever as a study of natural colour. W. W. Caffyn in his Surrey landscape (112) and Terriock Williams' view of Honfleur have nice colour in a low key, and near them Carlton A. Smith in "Winter Fuel" has a clever figure subject. One of the largest and strongest landscapes is T. Sidney Steel's sombre hillside "Death of the Master Stag" (144), and in a very opposite French style is the sunny pastures of Philip E. Stretton (169), admirable in the drawing of the cattle.

Arthur Hacker's portrait of "Chas. F. M. Cleverly" (19), J. Herbert Snell's (54) feeling landscape, Jos. Clark's "Golden Wedding" (80), Louis Grier's charming impressionism, "The Quiet Waters of an English River" (95), J. J. Shannon's admirably painted portrait of a boy (97) are other pictures of merit. In the Central Gallery, the President's centre picture, "The Old Story," a gossip between young man and maid at an old cottage gate, is painted with much tenderness. Alfred East's "Norfolk Marshes" (248) is a delightful piece of broad handling and colour, and Ernest A. Waterlow's "Romney Marsh" (24) is truthful in its tone and colour. A good example of Edgar Bundy's power as a painter of incident is "The Sponging House," worthy of Teniers' brush. The man with pale and lejected countenance, with his arm round his wife, whose head rests on the table, and he gambling group in the rear of the apartment, are cleverly painted, and full of pathos. Charles E. Marshall's large picture, "Men were Deceivers Ever," is too artificial in subject and colour. James Orrock has two characteristic coast scenes, both from Holy Island, full of atmosphere, and of silvery-grey tone (257, 267). We come next to John R. Reid's "Toby's Rehearsal," an itinerant player and his little girl, in ancient costume, seated under an old tree, putting their dog through his part, strong in colour. Further on, Fred Roe's "Under Repairs" (276); a fine seascape, with fishing-boats, by Edwin Hayes, R.H.A.; Frank Colesey's "Trawlers," a large and clever sea-piece. The work of Frank Walton, "Barked Oaks Newly Thrown" (460), opposite the President's work, is a beautiful rendering of a woodland, in which the painter, a master of foliage, blends in charming and harmonious colouring the browns and greens, and gives us that sense of depth and mystery one discovers in a wood. The marvellous ramifications of the branches are dexterously depicted. T. B. Kennington paints a different phase of life than we have been accustomed to see from him. "Engaged" is a group of three delightfully insouciant young ladies in low evening dress,

one of them being questioned by her companions and displaying a natural shyness. The delicacy of the colour of the dresses and the whole handling shows that the painter has almost equal power of displaying character among the fashionable as among the poor and friendless. "La Coquette," by J. Henry Henshall (372), is also a clever study of eyes. A. D. Peppercorn's dark landscape of trees against a grey sky (377), Elias Bancroft's "The Nomad" (359) are pictures of interest. One of the most attractive pictures is E. Blair Leighton's "Where There's a Will, There's Always a Way," a fair and picturesquely-dressed young lady in 18th-century costume, unlocking a garden gate, while her lover stands waiting in a boat on the river. The tale is admirably told; the hilly distance and the harmony of colour perfect.

Mrs. Frank May's exquisite drawing "A Bit of Colour" (183), Geo. Morton's "He Cometh," and especially C. MacIver Grier's "Taking a Mean Advantage"—a well-told and amusing picture of an old gentleman asleep at the table in an inn parlour while his dog is helping himself to the fish on a plate, and a waitress smilingly watches near the door—are pictures of mark. F. Markham Skipworth (224), T. Noyes Lewis (243), Miss Edith M. Cameron, "Santa Cecilia" (286), are other contributors of note.

The East Gallery has only a few works of interest, and nothing very important in subjects. John Finnie, in his delicate study of lake reflection "Rydal" (420); J. Aumonier, in his sunlight on hill and meadow in a Sussex hayfield (422); Arnold Helcke, in a grey-toned coast view near Boulogne-sur-Mer (429); Alex Harrison, in "Moonlight" (430), have done good work. We cannot admire the rather grotesque imaginative frenzy Henry J. Stock has given us in his "Dream of the Worlds"—the sun and the planetary spheres before the gaze of a human soul represented standing on the brink of a precipice. John R. Reid's "A Gipsy Queen" represents a gipsy with her retinue passing through a village lane, strong in colour. "Zelica Supplanted" (472) is an Oriental figure-subject, cleverly conceived, and in delicate colour, by F. Markham Skipworth, and near it Edwin Hayes has one of his fine sunsets on a Dutch coast, excellent in colour. Below is a delicately-painted wave study by Harry E. J. Browne (475), and, further on, J. L. Pickering's "Dream of Home," an old house by lake, amidst ancestral trees, has some nice colour and sentiment. Edward Hargitt's "Rent Gathering" (498) is a fine study of a stormy sky in the Highlands. For atmosphere effects, few surpass Alfred East's "Clairwin Valley" (513), a large sunny landscape, veiled in thin mist. Stuart Lloyd has one of his riverside hamlets, "Sitlington, Sussex" (514). Edwin Harris's "Firstlings of the Year," a girl making a primrose bunch, is natural. A study by Anderson Hague, "In the Glen," is a delicious piece of rock and foliage through which a rivulet sparkles. E. M. Wimperis's "An Autumn Day" (537)—a stream meandering through a meadow—is one of his strongest landscapes. Probably the chief interest centres in A. Chevallier Taylor's "Confirmation Day"—a young girl in her veil preparing for the ceremony; she sits with her rosary in her hands, and near her small bedroom altar. In the same class is T. B. Kennington's cleverly-drawn and painted figure of a young lady clad in pale green looking through the "Marriage Column" (540). The brown background enhances the colour; but the chief merit of the work is the strong top-light, which catches and brightens her face and the folds of the silk dress. Fred G. Cotman's "Burst of a Storm" (549), and the soft, golden hues of foliage and scattered leaves in Ernest Par-ton's "Autumn Morning" (558), are worthy

of notice; to which we may add Yeend King's "Autumn's Robe" (597), a fine sylvan landscape of gold and red hues, and the Hon. J. Collier's clever-painted "In a Beech Wood," with the beech-trunk lying athwart the bed of brown leaves (625). Frank Calderon's "Parting" (607) is pathetic and well painted. Sir George Hare's "Ha! Ha! Ha!" (600) is a cleverly-painted negress' face, and there is also a brilliant and strongly-coloured picture of a slave-trader by F. Brangwyn.

STABILITY OF WALLS ON SOILS.—VIII.

PROBLEM OF PARALLEL FORCES ACTING ON WALL FOUNDATIONS.

THE different vertical loads and pressures acting through the walls of buildings upon the foundation-soil base are to be considered as so many parallel forces—i.e., forces acting in parallel directions, either in one or different planes, represented as concentrated at the axes of gravitation of their masses or of their supporting points. Their resultant must be ascertained by the rules for the resolution of parallel forces acting in the same plane. The corbelled or cantilever projecting features of a building, such as oriels, angle-turrets, balconies, &c., whose axis of gravitation of the overhanging portions pass outside the face of the supporting wall, must have their weights traced vertically through the plane of their static fulcrum or imposts. The moment of the projection or the leverage of action of such overhanging features which pass outside the face of the supporting wall does not increase the static reaction of the load upon the soil beyond its mere dead weight, as the leverage preponderance is counterbalanced by the mass of the wall, &c., to which it is structurally attached.

Analysis of Sectional Wall Loads.—In estimating the weights and dispositions of loads derived from the aggregation of materials of different densities, as they are usually arranged in various thicknesses when they make up the sectional width of the wall, it is necessary to separate these component loads, such as those of ashlar or stone facing, from the backing of common brickwork, which is less dense, so as to arrive at their resultant. The separate loads derived from stone or brick projecting cornices and blocking courses, also those of the various story stages of walls between wall benches, including those from the various floors, bressummers, and girders, and from roofs and any appendages thereon, and likewise those from any other contributory source of loading which are imposed upon the foundations, must be relatively located on the wall base, O O', Fig. 17, by the position of vertical arrows on the axes of gravitation, passing down through their centres of gravity, and intersecting the base line perpendicularly, all of which are indicated in Fig. 17.

Overhanging Features.—Then with regard to the position of the point or plane of reaction of overhanging features, or structural corbelling, an approximation may be roughly obtained by considering the overhanging mass, such as a stone cornice, to have its centre of gravity at one end of a lever, and that of the blocking course, counterbalancing it, at the other end, while the static fulcrum will be at some intermediate point in the cross section of the supporting wall. The position of this balancing fulcrum will be at a point inversely proportioning their leverages to the ratio existing between the respective masses. If the moment of the counterbalance were only equal to that of the overhanging weight, the slightest applied excess of weight or pressure would overturn it round the edge of the supporting wall. The counterbalance must, therefore, have sufficient excess of weight or of anchorage when the counterbalancing mass is partly below the level of the corbelling, in order to insure the necessary stability. The position of the point or plane of the static fulcrum must, therefore, lie inside of the face of the supporting wall, in order to impart stability, such as at the point (A) immediately below the bedding point of the cornice.

Corbelled Chimneys.—In the Metropolitan Building By-laws, 1855, s. 20 (1), chimneys are permitted to be built on corbels above the level of the ground-story ceiling, if the projection from the wall does not exceed the thickness of the wall in addition to it. The chimney being hollow, if symmetrical, would thus change the

axis of gravitation from the centre of the solid wall to a point near to its face, so that, apparently, it would have little stability. If, however, the chimney is corbelled in a wall which is not itself "corbelled out" on either side of it, it will derive more or less stability therefrom, depending on its character and lateral tenacity. If the wall remains solid throughout to which the chimney is corbelled, the stability is not endangered.

Relative Position of Component Loads.—The relative position of sectional resultants of the component loads of the various masses of the wall materials, and of the supporting points of floor and roof loads, is shown on a base of a diagram of the base, OO' , of the lower or basement wall, Fig. 17. The object is to find the centre of gravity of the sum of all the foundation loads. First, find the resultant of the loads imposed above the base of the wall, OO' . Second, find the loads added by the footings, concrete bed, &c., and their resultant, which is then placed symmetrically underneath the centre of gravity of the loads above them, as in Fig. 21. Then upon an enlarged copy of the diagram wall base, OO' , Fig. 17, drawn to a convenient scale, as Fig. 19, set down the relative values of the loads proportionately reduced to their smallest representative numbers, to simplify the computations, instead of being encumbered with large numbers in the operation. The final results can easily be restored to their proper values for further use. All weights or loads should be reduced to the same denomination, as tons, hundredweights, or pounds, as will be most convenient for scaling them on the diagrams. A scale with decimal subdivisions is convenient.

Resolution of Parallel Forces.—The problem of the resolution of parallel forces in its simplest form is solvable by the method of leverage—i.e., successively finding the relative positions and amounts of the resultants of adjacent pairs of forces, and in like manner combining their resultants for new resultants, and so on, until a final resultant is obtained. This resultant is equal to the sum of all the forces acting at its centre of gravity. The horizontal distance between the points of application of the forces is divided in the proportion of the forces to each other, and the resultant placed in an inverse order, so that the larger force has the less leverage from the resultant point.

Funicular Polygon of Forces.—But the graphic method of resolution by the funicular polygon of forces serves the same purpose in a ready manner. It may be noted in passing that the funicular polygon takes its name from the principle of action of a cord or rope suspended by its two ends, and loaded at various points with a number of weights, which may be either equal or unequal. If by the leverage principle just explained the weight, and the position of the centres of gravity of each subdivision of the analytical loads—as, for instance, those of each story-stage of the wall, and of the floors, &c., which rest upon each bench—has been found, as in Fig. 17, and that their representative ratios, as next explained, have been laid down to scale in a vertical line, as shown in Fig. 18; then suppose the loads per square inch to be all reduced to cwt.s., and if the numbers were yet too large, take, say, one-tenth part of each so as to get manageable figures, and proceed with the processes of resolution. To afford an easy illustration, take round numbers to thus represent the loads, with a decimal point introduced. Then upon an indefinite vertical line, as $A'B$, Fig. 18, measure off downwards by a convenient scale these representative loads as they follow each other in succession from right to left, or *vice versa*, on the wall-base, Fig. 19, and thus transfer them to the vertical load line $A'B$ in the same order.

Static Disposition of Structural Loads in different Cases.—The following four cases may be here noted as commonly met with in ordinary practice.

1. **Solid Walls with Floor Joists.**—Although the weights of floors having joist-ends inserted in the wall of ordinary construction, without pugging and soundboarding, in successive stories, when all are plaster-ceiled, may be the same for nominally like spans, their static effect on the cross section of the supporting foundation base will vary directly as the bearing centres of joists recede on the wall-benches. These differences of recessions of wall-benches necessarily affect their correct spans by so much. As regards the comparative weights of brick walls and such floors there can be no fixed ratio, as the weight of the

materials varies with their character, condition, and dimensions. Generally, however, the structural weight and the static equivalent of ordinary dwelling-floor loads would be about one-fourth of the weight of one and a half brick walls, solid throughout, not exceeding 10ft. of effective height to each floor. The resultant of these two sources of loading would in such a case be placed one-fourth of the distance between their respective centres of pressure nearer to the wall-centre of gravity. For each additional half-brick in thickness the ratio of floor weight to wall weight would be about one-twelfth less. Thus for two bricks thick the ratio = $\frac{1}{4} - 1 \cdot 12 = 1 \cdot 6$, with corresponding inverse leverages. This is only intended to afford a rough idea by inspection at a glance in viewing the relative positions of the common centres of gravity in the sectional diagram of walls and floors, Fig. 17.

2. **Solid Walls with Floor Girders.**—In the case of girders inserted in solid walls, and carrying considerable areas of floorage whereby a concen-

tration of weight is imposed at a few points, the ratio would be much reduced at its bearing-point on the wall, leaving its adjacent parts little affected thereby except through the horizontal tenacity of the wall.

3. **Fenestrated Wall Static Piers with Joists.**—The floor loads of inserted joist ends covering the bay portion of fenestrated walls are necessarily concentrated on the static pier portions of the wall. The adjustment of the foundation area must be made on this basis of independent piers supporting not only the intermediate bay-floor loads, but also those of the roof and of the spandrel or transom walls over the vertical tiers of window and door voids.

4. **Isolated Wall Piers Carrying Floor Girders.**—Care must be taken to compute the floor loads for those piers only with isolated foundations, which actually carry the girders. The adjustment of their foundation areas is to be made according thereto. When the fenestrated wall foundations are continuous, as they often erroneously are, instead of being isolated, all the bay-wall loads are structurally transferred to the static piers, which only should properly support all the loads. The reinforced support derived from the adjacent

bay foundations, when put in, depends upon the horizontal tenacity of the wall, the foundations become convex underneath the bay and concaved under the pier, while the masonry is yet in a green state.

What are Floor Loads on Foundations?—The mistake is sometimes made of allowing the recognised "strength" or computed stiffness safe-loads of the floor timber scantlings, such as $1\frac{1}{2}$ cwt. for dwellings for floor loads upon the foundations, but the actual static loads rarely, if ever, really amount to one-third of these computed "strength" loads. The actual dead structural loads, along with the usual imposed loads, together with average accidental loads, whether "dead" or "live," are only to be computed; otherwise a false resultant, both in amount and position, would be obtained, and the stability of the foundations be thereby impaired.

Description of Diagrams.—In accordance with the foregoing principles of estimating and locating the static value of the various loads, begin an enumeration of them with load No. 0, Fig. 19, representing that derived from the cornice and blocking course, assuming it all to be of uniform density. Next take load No. 5, derived from the roof, also taking account of the roof, gutter, and ceiling loads, and the remainder of the wall above the level of the templates. Then follow loads 4, 3, 2, and 1, including the weights of walls lying vertically between the benches of the story-stages, and of the several floors. There may be more than one included in each story stage, and of the loads supported by the floors. In a similar manner may be treated any number or manner of loads which may be derived from any other source that occurs in practice. As the whole of the load line $A'B$, Fig. 18, by scale, represents the total of all the vertical loads, less the footings, acting upon the foundation soil, it also represents the amount of their resultant acting through their united centre of gravity. In the example the vertical component of wind force is not allowed for. Only a few loads are treated to illustrate the details of the general process of procedure. It may be observed that when forces, as those due to weights, are all parallel to each other, the polygon representing these and their reactions becomes a straight line, having their common direction, but divided into segments proportionate to the several direct forces and their corresponding reactions, on the principle that the sides of the polygon are severally parallel to the directions of the forces which they represent. The upward reactions of the gravitating forces, as $A'N$, $N'B$, Fig. 18, complete the polygon. The common converging point, P , to which the lines in Fig. 18 radiate from the extremities of the several load-segments, $O5$, &c., to 1, is called the pole. The sides of the funicular polygon, Fig. 20, are drawn parallel to these converging lines, which respectively represent the amount of stress upon the cord between the points of application of the several weights. We may now briefly follow the process of constructing Fig. 18. Take as the pole any convenient point, P , on either side of the vertical load-line $A'B$, from which lines may radiate to both ends of all the load-segments $O5$, &c., to 1, without confusion. Draw these radial lines accordingly, PA , Po , $P5$, &c., to PB . Lay off on the horizontal line OO' , Fig. 19, representing the width of the wall base, the relative positions of the several loads, according to the method of analysis already explained. Through the extremities of this base-line, and likewise through the several load-points, wo , $w5$, &c., to w' , draw indefinite perpendicular dotted lines, OA' , woO , &c., to $O'B'$. In OA' , take any structurally convenient point, A' , Fig. 20, and through it draw the oblique line $A'O'$ parallel to the radial line AP , Fig. 18, and intersecting the vertical dotted line woO in the point O' , and then produce it indefinitely beyond; next through the intersecting point O' , Fig. 20, draw the line $O'5'$ parallel to OP , Fig. 18, and intersecting the $w55'$, in the point $5'$. In a similar manner proceed with the construction of the remaining sides of the funicular polygon, Fig. 20, parallel to the remaining radial lines of Fig. 18, each side terminating at the point of its intersections with the verticals, except the line $I'B'$, which is indefinitely produced to intersect the previous extension of $A'O'$ in the point G . A vertical line, Gr passing through this last intersection perpendicular to OO' , intersects the wall base in the point r , and gives the position of the point of application of the resultant of all its loads as above. A line drawn from P , Fig. 18, parallel to $A'B'$, Fig. 20, to intersect the load

MONTAUK CLUB-HOUSE, BROOKLYN, NEW YORK.

line, A B in the point N, divides it into its reactions at the extremities A and B, equal to A N and N B, measured by the scale of the load line. It is equal to the sum of the loads. The lines A' G, G' B', Fig. 20, represent funicular action by the position assumed by a cord suspended at the points A' B', with a weight attached at a corresponding point, G.

Example.—If the unit-pressure at the wall base be three tons per square foot of its horizontal section per lineal foot of wall, and that the soil has only a safe bearing power of one ton per square foot, then it is seen by the table p. 518 that four footing courses with offsets equal to one-fourth of the wall base will effect the necessary spread of the area of the foundations. Then, by means of the table at p. 420, giving the proportionate offsets in terms of the thickness of footing courses for various materials, a close approximation to the amount of the addition requisite to be made to the wall loads for the weight of the footings, and from these data to derive final corrections for foundation area to adjust the ultimate unit pressure of the footing base to the safe bearing power of the soil in question. The geometrical centre of the cross-section of the footings thus obtained, which are symmetrical, must be placed vertically underneath the centre of gravity of the wall loads previously obtained, so that the first resultant of wall loads and second resultant of footing weights coincide in the same vertical axis, and thus produce uniform pressure all over the footing area upon the underlying soil. The position that the resultant of the wall loads r , Fig. 22, is here assumed to strike the footing base of the house wall in as it may be designed according to the Metropolitan Building By-laws, first schedule (8), and which is the ordinary arrangement of the offsets, stands about one-twelfth of the breadth of the base to the left side of its geometrical centre, C, which will cause an unequal distribution of pressure, as it will be more intense on the left side, which represents the shorter arm of a lever, causing it to sink deeper in the soil, than on the right side, representing the longer arm. The corrected position of the footings necessitates their being

moved bodily this eccentric distance towards the left-hand side, so that the relation of the wall-base to the footings will be changed from the position of the wall-base shown at A, Fig. 21, to that shown by the section B, which consequently overlaps the top footing course on the right-hand side. The arrow $e' r'$ indicates this new relation, whereby the geometrical centre of the footing base is brought vertically underneath the resultant of the wall-loads r , and thereby equalises the pressure upon the soil underlying the base of the foundations. Fig. 22 shows the footings drawn symmetrically within the extreme verticals, drawn down from the wall-base, showing the relative position of the resultant r , drawn directly from G, and showing eccentric action upon the usual symmetrical footing-base, as arranged by rule-of-thumb. In cases of great eccentricity of the resultant of the wall-loads r , it may be necessary to readjust some of the offsets on either side of the footings, so that their transverse strength shall be equalised at such points of eccentric wall-loading.

(To be continued.)

MONTAUK CLUB-HOUSE, BROOKLYN, NEW YORK.

[WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.]

THE instructions to competing architects were to cover a plot 50ft. by 90ft. The prominent position which this building was to occupy, being near the entrance to Prospect Park, one end, the one with the large bay, bordering on the Plaza Circle, a favourite drive of Brooklyn people of an afternoon, called for a building of some architectural effect. The prevailing style of the private residences in the vicinity is the Romanesque. This made it imperative that the club should "change off" if it desired to hold up its head very proudly and prominently in the midst of so much richness of detail as had been portrayed in the Romanesque. There seemed to the architect much in Venice which might be adapted, as balconies and loggias belong as much to his climate as Venice, and American club houses are

not complete without them. The style afforded strong colouring in the materials used, although in this instance violent contrasts were avoided. In the first story alternate colours of brown sandstone and the English Runcorn stone are used, but barely distinguishable, although enough to give texture to the wall surface. Above is used a yellowish red brick, the relief work in red and buff terracotta, the buff predominating. The roof is covered with vitrified Spanish tiles of a dark reddish brown, harmonising with the wall treatment and presenting a strong sky-line. The balcony at the fourth story level encircles the building and is of metal. The most prominent terracotta enrichment is the frieze just under this balcony. The subject was suggested by the name of the club, which name belongs to a tribe of Indians who were settled in this region before the colonial times. The subject begins with mythologic and legendary stories of these Indians, and ends with pictures suggested by colonial history. The figures are of yellow with a red background. In the arrangement of the interior the intention was to place in the basement the bowling alleys, on the first story the conversation and morning rooms, the second the billiard and card rooms, the third various dining rooms, including the ladies' dining-room and ladies' parlour, the fourth the sleeping apartments with a "jolly room," so called, where it is expected members will retire for quiet chats and smokes. On this floor is the kitchen and pantries, connected by dumb waiters with the serving rooms and dining rooms in the story under. Thus each story has its purpose. On the first one enters and holds conversation, above he plays his games, up another flight of stairs he dines, and when he would steal away for quiet enjoyment with some boon companions, the fourth floor with its "jolly room" awaits him. From the billiard-room is a loggia connecting with an open balcony, from the dining-room there is another balcony, and the fourth floor has the broad balcony which encircles the building for a promenade. The first floor is finished entirely in mahogany, the second story in oak, and the third treated in white and gold. After an

occupancy of over a year, the arrangements have been found all that could be desired, and seems to secure the perfection of a social club-house.
F. H. KIMBALL, Architect, New York.

IRONMONGER (continued).

SAFES AND IRON DOORS (delivered only)—	
24 by 18 by 18, ordinary good quality safe, wrought-iron cases, three bolts, and lever lock, and having one drawer inside	each 7 10 0
24 by 20 by 20 ditto with two drawers and a partition	ditto 8 15 0
28 by 22 by 22 ditto ditto	ditto 9 10 0
30 by 24 by 22 ditto ditto	ditto 10 10 0
33 by 24 by 24 ditto ditto	ditto 11 11 0
36 by 24 by 24 ditto ditto	ditto 12 15 0

8ft. by 2ft., wrought-iron door 3in. thick, hung in 3in. by 3in. frame, with 2 1/2 in. by 3in. rebate bar, 3 1/2 in. filled lock-case, and fitted with brass lever handle, to throw four bolts, and having three fixed bolts at back, and secured by seven-sided, unpickable, gunpowder-proof locks, protected by hardened steel plates	ditto 12 15 0
8ft. 6in. by 2ft. 6in. ditto ditto	ditto 14 0 0
8ft. 6in. by 3ft. 6in. ditto ditto	ditto 15 15 0
8ft. 6in. by 2ft. 9in. ditto ditto	ditto 16 0 0
8ft. 6in. by 2ft. 6in., special strong-room door, 3in. thick, fitted with good lever lock, four bolts in front and three at back	ditto 8 0 0

7ft. by 3ft., sliding warehouse doors (Smith and Stevens') of 1/2 plates, with 1/2-plate stiles and rails, hung with strong wrought-iron straps, with turned 6in. pulleys, running on wrought-iron top bar A-shaped, and with guiding grooved hasp, staple, and loop handles	ditto 5 0 0
7ft. by 4ft. ditto ditto	ditto 6 10 0
7ft. by 5ft. ditto ditto	ditto 8 5 0
7ft. by 6ft. ditto ditto	ditto 9 10 0
8ft. by 4ft. ditto ditto	ditto 7 10 0
8ft. by 5ft. ditto ditto	ditto 9 10 0
8ft. by 6ft. ditto ditto	ditto 11 5 0
8ft. by 7ft. ditto ditto	ditto 13 0 0
8ft. by 8ft. ditto ditto	ditto 15 0 0

8ft. by 3ft., swing door, with middle and bottom rail, and hung in wrought-iron frames of 3in. by 3in. with 2in. by 3in. rebate bars, and fitted with good lever deadlock and two-barrel bolts	ditto 8 8 0
8ft. by 3ft. 6in. ditto ditto	ditto 9 8 0
8ft. by 4ft. ditto ditto	ditto 10 8 0
7ft. by 3ft. ditto ditto	ditto 9 8 0
7ft. by 4ft. ditto ditto	ditto 11 14 0
7ft. by 5ft. ditto ditto	ditto 14 0 0
8ft. by 4ft. ditto ditto	ditto 12 10 0
8ft. by 5ft. ditto ditto	ditto 16 0 0
8ft. by 6ft. ditto ditto	ditto 19 4 0

(The larger sizes are made as pairs of doors.)

8ft. by 2ft., fire and thief-resisting (special quality), with 3in. door-plates, 3in. by 2 1/2 in. rebate bar, 3in. frame, four front bolts, and three dogs at back, patent unpickable lock, two keys	each 12 15 0
8ft. 6in. by 2ft. 6in. ditto ditto	ditto 14 0 0
8ft. 6in. by 3ft. ditto ditto	ditto 15 15 0
8ft. 6in. by 2ft. 9in. ditto ditto	ditto 15 10 0
8ft. by 2ft. ditto, extra quality, throwing four bolts at front, and four at back, big brass handle	ditto 14 15 0
8ft. by 2ft. 6in. ditto ditto	ditto 16 5 0
6ft. by 3ft. ditto ditto	ditto 17 10 0
6ft. by 2ft. ditto, doorplates 3in., and frame and rebates 3in.	ditto 18 12 0
6ft. by 2ft. 6in. ditto ditto	ditto 18 5 0
6ft. by 3ft. ditto ditto	ditto 19 12 0
6ft. by 2ft. ditto, with 3in. doorplates and 3in. rebates and frames	ditto 17 15 0
8ft. by 2ft. 6in. ditto ditto	ditto 19 6 0
8ft. by 3ft. ditto ditto	ditto 20 12 0
8ft. by 2ft. ditto, with all plates 3in.	ditto 19 5 0
8ft. by 2ft. 6in. ditto ditto	ditto 21 0 0
8ft. by 3ft. ditto ditto	ditto 22 18 0

(The above are fireproof; they are about 15 per cent. less if not fireproof.)

HOBBS AND CO.'S Safes and Doors. (Take 10 per cent. off all "Hobbs'" safes, &c., that follow, delivered on ground floor only.)

FIRE-RESISTING Safes and Chests—

22 by 16 by 16, no inside fittings	each 7 0 0
24 by 18 by 18 ditto ditto	ditto 8 5 0
26 by 20 by 20 ditto ditto	ditto 9 7 0
28 by 22 by 22 ditto ditto	ditto 10 0 0
30 by 24 by 24 ditto ditto	ditto 12 13 0

CUPBOARD Stands—

Stands for safes of the following dimensions and 28in. high, door paneled, and sides, and fitted with lever locks, fixed in place:

23 by 17 by 17, with cornice and moulded base	each 1 16 0
25 by 19 by 19 ditto ditto	ditto 1 19 0
27 by 21 by 21 ditto ditto	ditto 2 3 0
29 by 23 by 23 ditto ditto	ditto 2 5 0
31 by 25 by 25 ditto ditto	ditto 2 6 0
33 by 27 by 27 ditto ditto	ditto 2 7 6
37 by 28 by 27 ditto ditto	ditto 2 11 0
45 by 28 by 27 ditto ditto	ditto 2 13 0

* All rights reserved by the Author.

STRONG SKELETON Frame Safe Stands—	
23 by 17 by 17, fixed to floor	each 0 15 6
25 by 19 by 19 ditto	ditto 0 17 6
27 by 21 by 21 ditto	ditto 0 17 6
29 by 23 by 23 ditto	ditto 0 18 9
31 by 25 by 25 ditto	ditto 0 19 6
33 by 27 by 27 ditto	ditto 1 0 6
37 by 28 by 27 ditto	ditto 1 3 0
45 by 28 by 27 ditto	ditto 1 4 0

GUNPOWDER and Ammunition Safes—	
87 by 23 by 27, outside, to hold 2cwt. of powder	ditto 20 0 0

SEAMLESS Fire-Resisting (single door)

Book Safes, no inside fittings—	
23 by 17 by 17, delivered on ground floor	ditto 9 5 0
25 by 19 by 19 ditto	ditto 10 10 0
27 by 21 by 21 ditto	ditto 12 0 0
29 by 23 by 23 ditto	ditto 14 10 0
31 by 25 by 25 ditto	ditto 16 10 0
33 by 27 by 27 ditto	ditto 18 10 0
37 by 28 by 27 ditto	ditto 21 10 0
23 by 27 by 27 with 2 drawers	ditto 11 0 0
25 by 19 by 19 ditto	ditto 12 10 0
27 by 21 by 21 ditto	ditto 14 10 0
29 by 23 by 23 ditto	ditto 16 10 0
31 by 25 by 25 ditto	ditto 18 10 0
33 by 27 by 27 ditto	ditto 21 0 0
37 by 28 by 27 ditto	ditto 23 10 0

FIRE-RESISTING single-door Book-Safes—	
25 by 19 by 19 with 2 drawers at bottom	ditto 16 10 0
27 by 21 by 21 ditto	ditto 18 15 0
29 by 23 by 22 ditto	ditto 21 0 0
31 by 25 by 25 ditto	ditto 24 0 0
33 by 27 by 27 ditto	ditto 27 5 0
37 by 28 by 27 ditto	ditto 29 15 0
45 by 28 by 27 D-pattern, having two drawers and one division, throwing four front bolts in front	ditto 59 10 0
53 by 31 by 27 M-pattern	ditto 43 0 0
61 by 33 by 27 D-pattern, two drawers and two shelves	ditto 59 0 0
Ditto ditto one shelf	ditto 58 5 0
Ditto ditto one long drawer, two short, and a shelf	ditto 63 0 0

SEAMLESS fire-resisting, double-door

Book-Safes—	
37 by 35 by 27 H H pattern, two drawers at bottom, two partitions, and shelf	ditto 42 10 0
49 by 37 by 27 two drawers in middle	ditto 55 0 0
58 by 43 by 30 ditto at bottom, two shelves above	ditto 79 0 0
69 by 55 by 30 ditto three drawers in middle and one cupboard at top with double doors	ditto 108 0 0
85 by 63 by 30 ditto six drawers in middle, four upright partitions, and two cupboards at top	ditto 139 0 0

EXTRA-STRONG, seamless, fire-resisting, single-door, clutch-bolt steel Safes, rust, damp, fire, and thief resisting—

25 by 19 by 19 no fittings and having clutch-bolts all round	ditto 24 10 0
27 by 21 by 21 ditto	ditto 26 15 0
29 by 23 by 23 ditto	ditto 29 10 0
31 by 25 by 25 ditto	ditto 34 0 0
33 by 27 by 27 ditto	ditto 38 0 0
37 by 28 by 27 ditto	ditto 44 0 0
27 by 21 by 21 ditto with 2 drawers	ditto 29 10 0
29 by 23 by 23 ditto	ditto 33 0 0
31 by 25 by 25 ditto	ditto 37 0 0
33 by 27 by 27 ditto	ditto 42 0 0
37 by 28 by 27 ditto	ditto 47 0 0
45 by 28 by 27 ditto and one shelf	ditto 53 0 0
53 by 31 by 27 ditto	ditto 64 0 0
61 by 33 by 27 ditto	ditto 73 0 0

DOUBLE-DOOR ditto—

37 by 35 by 27 with 9-lever lock and protected with cheek lock for dual custody and 1 1/2 welded iron and steel plates to resist drilling	ditto 55 0 0
49 by 37 by 27 two drawers at bottom, two partitions, and one shelf above	ditto 77 0 0
58 by 43 by 30 two drawers and two shelves	ditto 104 0 0
69 by 55 by 30 three drawers in middle and one cupboard at top, with double doors	ditto 148 0 0
85 by 63 by 30 six drawers in middle, four upright partitions, and two cupboards at top, double doors	ditto 187 0 0

DOORS and FRAMES for strong-rooms,

quality No. 2—	
5ft. 6in. by 2ft. 2in. with angle-iron frames	ditto 17 0 0
6ft. 6in. by 2ft. 6in. ditto	ditto 18 0 0
6ft. 6in. by 2ft. 9in. ditto	ditto 20 0 0
6ft. 6in. by 3ft. 6in. ditto	ditto 23 0 0
7ft. 6in. by 3ft. 6in. ditto	ditto 25 0 0
6ft. 6in. by 2ft. 6in. ditto quality No. 3	ditto 25 0 0
6ft. 6in. by 2ft. 9in. ditto	ditto 29 0 0
6ft. 6in. by 3ft. 6in. ditto	ditto 31 0 0
6ft. 6in. by 3ft. 6in. ditto	ditto 34 0 0
7ft. 6in. by 3ft. 6in. ditto	ditto 36 0 0

These doors are provided with two Hobbs 8-lever locks for dual custody.

6ft. 6in. by 3ft. 6in. patent clutch-bolts with two locks (9-lever)	ditto 33 0 0
6ft. 6in. by 2ft. 9in. ditto	ditto 35 10 0
6ft. 6in. by 2ft. 9in. ditto	ditto 38 0 0
6ft. 6in. by 3ft. 6in. ditto	ditto 41 0 0
7ft. 6in. by 3ft. 6in. ditto	ditto 43 10 0

VENTILATING GATES and Frames—

6ft. 1 1/2 in. by 2ft. 7 1/2 in. outside frame, and light quality	ditto 8 5 0
6ft. 4 1/2 in. by 2ft. 10 1/2 in. ditto	ditto 9 5 0
6ft. 7 1/2 in. by 2ft. 10 1/2 in. ditto	ditto 10 10 0
6ft. 10 1/2 in. by 3ft. 1 1/2 in. ditto	ditto 11 15 0
7ft. 1 1/2 in. by 3ft. 1 1/2 in. ditto	ditto 13 10 0
6ft. 1 1/2 in. by 2ft. 7 1/2 in. ditto	ditto 12 10 0
6ft. 4 1/2 in. by 2ft. 10 1/2 in. ditto	ditto 13 10 0
6ft. 7 1/2 in. by 2ft. 10 1/2 in. ditto	ditto 15 0 0
6ft. 1 1/2 in. by 3ft. 1 1/2 in. ditto	ditto 17 0 0
7ft. 1 1/2 in. by 3ft. 1 1/2 in. ditto	ditto 18 10 0

CHUBB'S SAFES (jeweller's)—

2ft. 6in. by 1ft. 7in. by 1ft. 6in. delivered only, with diagonal bolts all round the doors	each 32 0 0
Ditto ditto with two shelves	ditto 33 0 0
Ditto ditto with one drawer	ditto 34 0 0
2ft. 2in. by 1ft. 8in. by 1ft. 8in. no fittings	ditto 35 0 0
Ditto ditto two shelves	ditto 35 10 0
Ditto ditto 1 drawer and shelf or 1 division	ditto 37 0 0
2ft. 4in. by 1ft. 10in. by 1ft. 10in. no fittings	ditto 38 15 0
Ditto ditto 2 shelves	ditto 39 5 0
Ditto ditto 1 drawer and division or shelf	ditto 40 10 0
2ft. 6in. by 2ft. 6in. by 1ft. 11in. no fittings	ditto 42 0 0
Ditto ditto 2 shelves	ditto 42 10 0
Ditto ditto 1 drawer and division	ditto 43 15 0
2ft. 9in. by 2ft. 2in. by 2ft. no fittings	ditto 40 10 0
Ditto ditto 2 shelves	ditto 47 0 0
Ditto ditto 2 drawers and shelf	ditto 49 15 0
Ditto ditto 1 division, 1 drawer, and 1 shelf	ditto 43 10 0
Ditto ditto 1 division, 1 shelf	ditto 43 5 0
2ft. 7in. by 2ft. 3in. by 2ft. 2in. 2 drawers, shelf, and division	ditto 51 10 0
2ft. 10in. by 2ft. 4in. by 2ft. 3in. ditto	ditto 54 10 0
3ft. 6in. by 2ft. 3in. by 2ft. 1in. no fittings	ditto 53 10 0
Ditto ditto 2 shelves	ditto 51 5 0
Ditto ditto ditto and 1 drawer	ditto 53 5 0
Ditto ditto 1 division, 1 shelf, and 2 drawers	ditto 55 0 0
3ft. 4in. by 2ft. 4in. by 2ft. 1in. no fittings	ditto 50 0 0
Ditto ditto 2 shelves	ditto 58 0 0
Ditto ditto ditto and 2 drawers	ditto 59 0 0
Ditto ditto 3 drawers 1 division	ditto 60 0 0
Ditto ditto fitted with a solid coffer of hard steel and wrought iron	ditto 75 10 0
3ft. 8in. by 2ft. 6in. by 2ft. 2in. 3 shelves	ditto 64 0 0
Ditto ditto 3 drawers 1 division	ditto 67 10 0
4ft. 2in. by 2ft. 6in. by 2ft. 2in. 3 shelves (shifting)	ditto 70 0 0
Ditto ditto 1 shelf and 3 drawers	ditto 73 10 0
4ft. 8in. by 2ft. 6in. by 2ft. 3in. 8 shelves	ditto 78 0 0
Ditto ditto 1 division 2 shelves	ditto 81 10 0
5ft. 2in. by 2ft. 8in. by 2ft. 3in. 1 shelf	ditto 93 10 0
3 drawers	ditto 93 10 0
2ft. 11in. by 2ft. 7in. by 1ft. 11in. double door, 2 drawers, 1 shelf and 1 division	ditto 70 10 0
Ditto ditto divided into 2 safes, and having 1 shelf and 2 drawers	ditto 81 0 0
3ft. 4in. by 2ft. 11in. by 2ft. 1in. 2 divisions, 2 shelves, and 2 drawers	ditto 83 0 0
3ft. 4in. by 2ft. 11in. by 2ft. 3in. (in two)	ditto 97 0 0
3 shelves and 3 drawers	ditto 97 0 0
3ft. 8in. by 3ft. 2in. by 2ft. 2in. 2 divisions, 2 shelves, and 2 drawers	ditto 91 0 0
3ft. 8in. by 3ft. 2in. by 2ft. 5ft. (2 safes)	ditto 109 0 0
2 shelves, 3 drawers	ditto 109 0 0
4ft. 2in. by 3ft. 6in. by 2ft. 8in. 2 divisions, 1 shelf, 4 drawers	ditto 106 0 0
4ft. 2in. by 3ft. 6in. by 2ft. 7in. (2 safes)	ditto 129 0 0
2 shelves, 4 drawers	ditto 114 10 0
4ft. 2in. by 4ft. 2in. by 2ft. 5 divisions, 2 shelves, 3 drawers	ditto 132 0 0
5ft. 2in. by 3ft. 6in. by 2ft. 4in. 2 divisions, 2 shelves, 2 drawers	ditto 132 0 0
5ft. 8in. by 4ft. 2in. by 2ft. 4in. 3 divisions, 2 shelves, 3 drawers	ditto 173 0 0
6ft. 2in. by 3ft. 8in. by 2ft. 4in. 2 divisions, 1 shelf, 5 drawers	ditto 171 0 0
6ft. 8in. by 3ft. 10in. by 2ft. 6in. 3 divisions, 2 shelves, 5 drawers	ditto 196 0 0
7ft. 2in. by 4ft. 2in. by 2ft. 8in. 5 divisions, 1 shelf, 10 drawers	ditto 217 0 0

BEST QUALITY, Bankers' Safes, fitted with wheel locks throwing bolts all round the doors (diagonal bolts).

2ft. by 1ft. 7in. by 1ft. 6in. as above	ditto 51 5 0
Ditto ditto 2 shelves	ditto 53 10 0
Ditto ditto 1 drawer	ditto 52 0 0
2ft. 2in. by 1ft. 8in. by 1ft. 8in. no fittings	ditto 55 15 0
Ditto ditto 2 shelves	ditto 56 0 0
Ditto ditto 1 shelf, 1 drawer, 1 division	ditto 57 10 0
2ft. 4in. by 1ft. 10in. by 1ft. 10in. no fittings	ditto 62 5 0

ROBERT BOYLE AND SON, LIMITED.

THE directors of Robert Boyle and Son, Limited, ventilating engineers, London and Glasgow, have resolved to recommend a dividend of 12½ per cent., free of income-tax, for the year ending September last, after placing to the reserve fund one-sixth of the profits earned and carrying forward £1,386 4s. 9d. This makes the seventh dividend, 12½ per cent. being paid for the last three years, and 12 per cent. for the previous years. The directors propose that the dividend for the current year will balance the subscribed capital of the company, including the ordinary shares held by the vendor, when cent. per cent. will have been paid.

The business done during the year has been considerably in excess of the previous year, though that was the most profitable year since the formation of the company. The directors attribute this success, and their consequent ability to pay such a handsome dividend, to their constant study of the requirements of architects, and to the great and ever-increasing demand for the latest improved form of the self-acting air-pump ventilator, which, though much superior in design, make, and action, is now sold at 50 per cent. less than previous and inferior forms, constituting it not only the most efficient and ornamental, but the cheapest, ventilator in the market.

The company have at present some very important contracts in hand at home and abroad, including the largest ventilating contract they have ever received from the British Government, and a contract of equal magnitude for the Spanish Government.

Mr. Robert Boyle has recently visited the East and Australasia, and has established agencies in Burmah, Queensland, New South Wales, Victoria, South Australia, and New Zealand, arrangements having also been made for the manufacture of the different ventilating and

sanitary appliances in each of the Australian colonies and New Zealand. Mr. Boyle has surveyed and submitted plans for the ventilation of the new Jubilee Hall, Rangoon; King of Siam's Palace, Bangkok; Government Buildings and Museum, Batavia; the Chicago Exhibition buildings; Houses of Parliament, Centennial Hall, Municipal Buildings, new Hospital, and new Theatre, Sydney; Houses of Parliament, Stock Exchange, Commercial Bank, and Bank of Victoria, Melbourne; also for the complete ventilation of the new drainage scheme, Melbourne. At Adelaide the air-pump ventilators have been applied to the Houses of Parliament, Government House, Government Buildings, Supreme Courts, Post-office, Hospital, Art Gallery, Museum, University, and other public buildings. At Christchurch, New Zealand, the house drainage is exclusively ventilated with the air-pump ventilators. They are also applied to the Houses of Parliament, Government House, Government Buildings, Post-office, Supreme Courts, Hospital, Opera-house, &c., Wellington.

"BUILDING NEWS" DESIGNING CLUB.

AWARD OF PRIZES, SESSION 1890-91.

THE fifteenth year of our Designing Club has now concluded, and the following subjects were thus competed for by members:—

A.—Convalescent Home.—"Smilash the Goth," 1; "Ayrshire," 2; "McGinty," 3; "Hilarious," 4; "Symbol," 5.

B.—A small House for an Artist, with Studio.—"Vulcan," 1; "Smilash the Goth," 2; "Cotonopolitan," 3; "McGinty," 4; "Jean," 5.

C.—A Parish Hall.—"Nil Nisi Bonum," 1; "Smilash the Goth," 2; "Vulcan," 3; "Firefly," 4; "Unitate Fortior," 5.

D.—Dining-room Chiffonier and Chair.—"Smilash the Goth," 1; "Nil Nisi Bonum," 2; "Black Prince," 3; "Cruiser," 4; "Signor C.," 5.

E.—Pair of Labourers' Cottages.—"Vulcan," 1; "Van Demon," 2; "Symbol," 3; "Smilash the Goth," 4; "McGinty," 5.

F.—A small Post-office for a Country Town.—"Smilash the Goth," 1; "Vulcan," 2; "Nil Nisi Bonum," 3; "Unitate Fortior," 4; "Nimrod," 5.

G.—A Drawing-room Cabinet.—"Smilash the Goth," 1; "Vulcan," 2; "Nil Nisi Bonum," 3; "La Cigale," 4; "Black Prince," 5.

H.—A Summer house.—"Vulcan," 1; "Smilash the Goth," 2; "Nil Nisi Bonum," 3; "Unitate Fortior," 4; "Pastime," 5.

I.—A Seaside Bath-house.—"Vulcan," 1; "Smilash the Goth," 2; "Unitate Fortior," 3; "Firefly," 4; "Neufardi," 5.

J.—A Highland Shooting-box.—"Vulcan," 1; "Nil Nisi Bonum," 2; "Smilash the Goth," 3; "Unitate Fortior," 4; "Black Prince," 5.

From the above list it will be seen that "Smilash the Goth," coming 4 times 1st, 4 times 2nd, once 3rd, and once 4th, takes the leading prize, having obtained a foremost position on every occasion, and contributed a design for each subject. The second prize is secured by "Vulcan" with 5 firsts, 2 seconds, and 1 third. "Nil Nisi Bonum" wins the third prize by being once 1st, twice 2nd, and three times third. Hon. mention is obtained by "Unitate Fortior," who ranks 4th (C. H. B. Quennell, 44, Lower Kensington-lane), and "McGinty" (J. E. Goodacre, Manor-road, Liscard, Cheshire), who comes in fifth.

The following prizes are therefore awarded accordingly:—

"Smilash the Goth" (G. L. Morris, 59, Blomfield-road, Maida Hill, W.), £10 10s.
"Vulcan" (name and address wanting), £5 5s.

"Nil Nisi Bonum" (W. A. Forsyth, The Studio, Finchley New-road, N.W.), £3 3s.

CONDITIONS FOR 1891-1892.

The following list of rules must be observed in every particular by all competitors:—

1. Drawings to be sent in 28 days after the publication of the list of subjects.
2. Usually two subjects will be given every month, from which a competitor may choose.
3. The drawings to be executed in firm black lines on white drawing-paper, in sheets of the

absolute size of 22in. by 14in., with no washes or tinting in colour whatever. Outline to be the first consideration; but drawings may be slightly shaded with shadows executed wholly in line. Sectional parts to be shown in ruled "hatching" or blocked in. The scale to be used will be given with each subject.

4. Drawings to be forwarded unmounted, by post, care being taken to roll the short way of the drawing, as packages over 18in. long are not transmissible by book post.

5. On entering the class (which may be done at any time), each competitor is required to furnish his name and address, which must be written legibly on the back of each drawing, as a guarantee of good faith, the *nom de plume* the author intends to adopt being boldly marked on the front of each separate drawing.

6. Prizes of £10 10s., £5 5s., and £3 3s. will be awarded to the best series of designs, each series not to consist of less than six subjects. Our decision to be final.

7. Before awarding the prizes any contributor will be expected to furnish proof, if necessary, as to his age, and the time during which he has been engaged in professional pursuits, though no candidate need be strictly an architectural student.

8. We reserve the right of arranging the drawings for publication in any manner we deem necessary.

9. A critical notice of the designs sent in of each series will be given in an early issue following the receipt of the drawings.

FIRST LIST OF SUBJECTS.

A.—Local Board Offices for a country village in a stone district. Site to be an isolated one facing west, with a road frontage on front and right-hand only. Accommodation to comprise office for surveyor, with drawing office for one clerk. A pair of rooms for the clerk to the local board, one being his public office for inquiries. A rate collector's office and a board-room for ten members, who will sit at a horseshoe-table. W.c.'s and lavatory to be provided, and a caretaker's residence, consisting of living-room, scullery, pantry, w.c., and two bedrooms. The size of the rooms is left to competitors. The board-room to be on the first floor, with the rooms of the clerk to the board. A strong room, 6ft. square, for his use to be provided. Caretaker's door to be at the rear of the premises, and his rooms may be on two floors at the back. Scale 8ft. to the inch. View, two elevations, section, and plan. Plans may be drawn to 16ft. to the inch, if necessary.

THE INNS OF COURT AND CHANCERY.*

ONE always wonders, much as Wesley did, why the devil had the best tunes, how the lawyers ever came to obtain possession of the pleasant nooks of London in which the Inns of Court are situate. Dear to the artist and antiquary, in spite of the vandalisms of the various benchers who bear away over them, one hopes sometimes that better masters may some day appreciate the Temple, Lincoln's Inn, and Gray's Inn as they deserve to be appreciated. Meanwhile the best consolation may be found in the possession of such a magnificently-illustrated record of their beauties as that before us. Mr. Loftie's work has been conscientiously performed throughout. He is rather merciless in some of his conclusions—is it so certain, for instance, that the famous catalpa tree in Gray's Inn Gardens was *not* planted by Bacon? or so utterly beyond all doubt that Mr. Douthwaite, the librarian and historian of Gray's Inn, is so at sea as Mr. Loftie thinks in his ancient history of his Inn? Anyhow, Mr. Loftie himself is always ready with chapter and verse for his own facts, and his style is as attractive as his story is veracious. He gives in turn a lucid history of each of the Inns and an intelligent running commentary on their respective beauties, and their associations with the famous men who have dwelt in them. Mr. Herbert Raiton's illustrations are perfect. He gives us twelve plates, ten of which are by himself, one by Mr. A. E. Pearce, and one by Mr. E. Stamp, and forty-five vignettes, mostly his own, but a few by the other artists named. The volume is sumptuously printed and well bound, and in every way a credit to the publishers.

* "The Inns of Court and Chancery." By W. J. LOFTIE, B.A., F.R.S.A. With many illustrations by HERBERT RAITON. (London: Seeley and Co., Limited.)

PETROUS TILES.

WE have had brought to our notice some very hard and extremely well-made tiles, manufactured by Messrs. Carter and Co., at their Encaustic Tile Works, Poole, Dorset, to which we desire to call the attention of architects, builders, and others. These "Petrus" tiles, as their name implies, are very stone-like in their texture, but much harder than any stone could possibly be. We have on our desk samples of five different colours—black, chocolate, red, grey, and buff. For finish and nice harmonious colour, they are not to be surpassed. These tiles are 3in. square; but they can be had in larger sizes 6in. by 6in., 4½in. by 4½in., and being so true in size and shape, are well suited to pavements of churches, public and private buildings, conservatories, lobbies, and other purposes where accurate fitting is required. For these purposes Messrs. Carter and Co. make diagonal halves and border strips of various widths, so that patterns of many varieties can be made. The colours are particularly quiet and artistic, and just those which architects prefer. The price of these tiles is only 3s. 6d. per square yard. We have seen other examples of the ornamental tiles made by this firm, and can recommend them to the profession. Messrs. Carter and Co. have successfully kept pace with the demand for artistic tile work, and their mosaic, mural tile work, faience, majolica dados, fireplaces, and other decorative applications are now well known for their quality and durability, and for the superiority they have over the manufacture of goods of this class, which appeal to a taste for bizarre and bright colours.

OBITUARY.

THE death is announced at the early age of thirty-two of Mr. Paul Peel, a distinguished Canadian artist, and a pupil of Gérôme. Mr. Peel was born at London, Ontario, where his father is a marble cutter and his sister a sculptor. His training began with three years at the Pennsylvania Academy of Fine Arts, was continued at the Royal Academy, and ended with five years in Paris. He had since resided at the French capital, with occasional visits to Canada, and had already obtained recognition in both countries. He leaves a widow and one son.

Mr. James Waterston, builder, of Morpeth, died on the 25th ult., after a long illness. Mr. Waterston was born in Edinburgh, where his father, who was a Morpeth man, was working as a mason in the building of the New Town. The deceased moved to Morpeth, and, following his father's trade, served his apprenticeship in the building of Meldon Hall. When he had served his time, he entered into partnership with his brother George, and these two acted for many years as the heads of the firm of Waterston Brothers. They were the builders of Cramlington, Otterburn, Longhirst, and many other Northumbrian churches, and they carried out the restoration in not a few notable churches, amongst them being that of St. Mary Magdalene, Mitford. Mr. Waterston was 70 years of age, and was widely known and respected among those of his trade.

The death of Mr. Robert Gray, builder and contractor, Berwick-on-Tweed, took place early on Friday morning. Mr. Gray, who was about 58 years of age, carried on a large business in Berwick and neighbourhood. At the time of his death he was engaged in the erection of houses on the ramparts as quarters for married soldiers under a contract with the War Office. A year ago Mr. Gray was elected a member of the town council as one of the representatives of the Middle Ward. He leaves a widow and family.

A SANITARY CRUSADE THROUGH THE EAST AND AUSTRALIA.*

MR. ROBERT BOYLE has reprinted the articles which recently appeared in our issues of September 2, 9, and 16, in a sumptuously-embellished little volume, and has added several illustrations. Thus, on the front of the cover we have a view of the Temple at Shway Dagon Pagoda, Rangoon; as the frontispiece, the grand entrance to the same; on the title-page the Royal Palace at Honolulu, and further on a group of leper beggars; the great

* Robert Boyle and Son, 64, Holborn Viaduct, and Glasgow.

recumbent figure of Buddha at Pegu; a curiously-balanced rock at Kut-te-yo, Burmah; the King of Siam's palace at Bangkok; a head-hunter, the Municipal Buildings and Centennial Hall at Sydney, the Houses of Parliament at Melbourne, and a ghastly but faithful representation of one of the "cannibal feasts" in the South Sea Islands. It is really wonderful how Mr. Boyle, whose thoughts while on foreign travel must of course be first occupied with his own large business, can find time to gather together the information he does; but the busy man is always the acute observer, and certainly Mr. Boyle seems never to have neglected an opportunity. Every reader who perused the articles in our pages will be glad to have them in this complete and dainty form.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—The session opened on the 1st inst., at which the president, Mr. W. Hale, F.R.I.B.A., delivered the annual presidential address. Mr. Hale congratulated the members upon the steadily increasing members, and on the improved position of the association, and expressed the hope that its work would, as it became more widely known, induce the members of the profession to give cordial support. Mr. Hale also said that though it had been found impossible for the association to do more this session than carry on the classes of design and construction, it was the wish of the council to see other special classes started in future sessions as soon as the number of students able to attend them justified their institution.

CHIPS.

The memorial to the late Mr. Edwin Waugh, the "Lancashire Burns," has just been completed, and has been erected on his grave in St. Paul's churchyard, Kersal Moor, Lancashire. The memorial takes the form of a Runic cross, standing on a die and plinth, and from the latter a ledger-shaped stone projects, covering the whole of the grave. The total height of the cross is about 10ft. The front of the cross is ornamented in high relief, and the whole is executed in grey Scotch granite. The front panel of the die bears the following inscription:—"Edwin Waugh. Born 29th January, 1817. Died 30th April, 1890." The work has been designed and executed by Messrs. J. and H. Patteson, of Oxford-street, Manchester.

As a memorial to the late Rev. Edward Thring, head master of Uppingham School, it was decided that the school chapel should be enlarged, and that a statue of the late head master should be placed therein. The extension of the chapel by the addition of a galilee was intrusted to Mr. A. E. Street, son of the architect of the chapel; the statue to Mr. T. Brock, R.A. The galilee, which was illustrated in the BUILDING NEWS for June 13, 1890, was completed and opened in September, 1890, Messrs. Parnell and Son, of Rugby, being the builders. On Tuesday last the statue was unveiled. It was exhibited at the Academy this year, and represents Mr. Thring seated, with a book in his right hand. It has been placed in the west end of the chapel.

The Morpeth town council considered last week the scheme drawn up by a committee appointed for the purpose of advising on the proposed working men's dwellings. They recommended that 30 houses be built on the West Greens, at an average total cost of £125 each house, or a total cost of £1,875, including everything. The committee recommended that they be let on such terms that they would at the end of 20 years become the absolute property of the tenants. The proposals were adopted.

New banking premises at Wiveliscombe were opened last week. The front is of Ham Hill stone. Mr. G. M. Silley, of London, was the architect, and Mr. Poole, of Ilminster, the builder.

The Princess Christian laid at West Brighton on Saturday the memorial stone of a new Police Convalescent Home in Bertram-road. Mr. Gibbins, of Brighton, is the architect of the building, which will cost £6,000.

A special meeting of the Manchester city council was held on Friday to consider the report of the consultative committee respecting the affairs of the Ship Canal Company. The report, which recommended that Parliamentary powers should be obtained for raising a further loan of two millions, was passed unanimously. On the same day the town council of Salford adopted a resolution in favour of lending £1,000,000 to the Manchester Ship Canal Company, if satisfactory conditions can be arranged.

THE MARLOW CLUB, GREAT MARLOW.—AUTOGRAPH DRAWINGS BY INIGO JONES, FROM THE DUKE OF DEVONSHIRE'S COLLECTION.—OXFORD CATHEDRAL.—SCHOOLS AT HOVE.—"SUNNY BANK," MAPPERLEY PARK, NOTTINGHAM.—MONTAUK CLUB HOUSE, BROOKLYN.—IMPROVED INDUSTRIAL DWELLINGS, GROSVENOR ESTATE, W.

Our Illustrations.

THE MARLOW CLUB, GREAT MARLOW, BUCKS.

THE Marlow Club building meets the requirements of a suitable club-house for the pleasure-seekers and lovers of sport who now so much appreciate the upper reaches of the river Thames. Those who know Great Marlow can realise the fine position against the existing suspension bridge. The principal floor, approached from the road and from the river bank, contains dining-room, reception-room, reading-room, writing-room, billiard-room, smoking-room, office, &c. The upper floors contain sleeping accommodation for nearly 100 members. The lower floor contains, at the back, the kitchen and usual domestic offices, and in the front a boat-house. The architect is Mr. Alfred Burr, F.R.I.B.A., of 85, Gower-street, W.C.

DRAWINGS BY INIGO JONES.

THE Duke of Devonshire has kindly lent us several of the original studies belonging to his famous collection of Inigo Jones's drawings, now at Chatsworth, and in the first instance brought together by the architect Lord Burlington, aided by Kent the architect. A few months ago a large number of these designs and drawings, on being removed from Chiswick House, now let to Dr. Tuke as an asylum, were exhibited in the galleries of the Royal Institute of British Architects, thus directing public attention to the subject, which cannot fail to be of interest to architects, particularly those who value their calling as an art. We gave the original perspective views of Inigo Jones's design for the great Palace at Westminster, showing the river and Whitehall fronts, in the BUILDING NEWS for December 19, 1884, and our illustrations were reproduced from the original drawings, which were lent us for the purpose by the kindness of H.M. the Queen from the Windsor collection. We likewise gave facsimiles of some designs by Inigo Jones for a series of capitals in our issue for January 30, 1885, and to-day we print a double-page plate of some more studies of the same character; but no two are exactly alike. Jones won the credit of being the first to introduce the Palladian style, though his earlier efforts, before he became Royal Surveyor, were in the direction of the Gothic manner then in vogue. None of his drawings of this earlier period of his career now exist seemingly, for, being unknown and comparatively obscure, no value was set upon his studies. Many of his drawings later in life were devoted to wild and fanciful conceptions for the scenery of Court plays at the time Jones held the appointment of Master of the Court Revels. They show, at any

rate, the brilliant imagination of Jones, and in the actual construction of the scenery he must have exercised considerable ingenuity. The talent for variety and freedom from the restrictions of Classical models evinced by these theatrical drawings is conspicuous also in the sketches for composite caps, which we have chosen for illustration to-day. They are all refined, and none are coarse or vulgar nor commonplace, and must be taken as an honest attempt on the part of a master hand to get away from the limits of past examples, though none can deny the purer beauty of the Grecian types, so dear to the purist. Such purity is out of place in the multifarious needs of much modern building.

CHRIST CHURCH CATHEDRAL, OXFORD.

THE new altar-piece in Oxford Cathedral, which we illustrate to-day, was erected a few years ago by Mr. G. F. Bodley, A.R.A., in red Dumfries stone, with dull-polished Rosso-Antico crucifix and statues in the niches. The side hangings are in green velvet embroidered with blue and gold thread, and are charming in tone and colour. The frontal hanging is in harmony with the rest of the work, and was carried out by the daughters of Dean Liddell. On the altar, which is of inlaid cedar, are two magnificent altar books mounted in silver gilt, very richly designed, and dated 1638. The candlesticks and silver alms-dish are about 20 years later in date, and are particularly good specimens of metalwork. The windows are by Mr. Burne-Jones, A.R.A. The views which we give show the choir as a whole and the sanctuary more in detail. We are indebted to Mr. Court Cole, of Folley Bridge, Oxford, for the beautiful photographs herewith reproduced. We gave a sketch of Cardinal Wolsey's fan-vaulting over the choir by Mr. Phené Spiers, F.S.A., in our issue for Aug. 29, 1890.

ROMAN CATHOLIC SCHOOL, HOVE.

THIS building, with the school-house attached, has recently been erected. It is built of stock bricks, the outer walls, being cavity walls, faced with red Cranleigh facings, and the roof covered with red Cranleigh tiles, the schoolrooms (65ft. by 25ft.), as well as the classrooms, being floored with Duffy's yellow deal wood-block flooring. The building was erected by Messrs. Parsons and Sons, of Hove, under the supervision and from the designs of Messrs. Lainson and Son, architects, of Brighton.

"SUNNYBANK," MAPPERLEY PARK, NOTTINGHAM.

THE illustration of this residence shows the actual background of trees, amongst which it is so beautifully and picturesquely situated. The house has been planned and carried out with great care, and is the private residence of Mr. Charles Hill, of Nottingham, the architect being Mr. Arthur W. Brewill, of Angel-row, Nottingham.

MONTAUK CLUB-HOUSE, BROOKLYN, N.Y.

(SEE description and further illustration on page 625.)

NEW INDUSTRIAL DWELLINGS, GILBERT-STREET, OXFORD-STREET.

ON Tuesday the Duke of Westminster opened two new blocks of dwellings for the working classes in Gilbert-street, Oxford-street. The buildings are the last of nine blocks of dwellings erected by the Improved Industrial Dwellings Company during the past six years on that part of the Duke's estate which lies between Grosvenor-square and Brook-street on the south, and Oxford-street on the north, the whole occupying an area, exclusive of streets, of nearly two acres. These buildings contain accommodation for 332 families, which, with the 38 families in Clarendon Building, Balderton-street—erected in 1872—represent a total of nearly 2,000 persons of the working classes resident on this part of the Grosvenor Estate, or about 700 more than formerly occupied rooms in the old houses. The total cost will be upwards of £80,000. Each dwelling contains separate domestic conveniences, and wash-houses are provided on the roofs. The company has, during the past 23 years, erected on other parts of the Grosvenor Estate 409 separate dwellings for about 2,000 persons. They possess, in all, 48 estates in various parts of the Metropolis, chiefly in the central and eastern districts, 47 of which are now completed for occupation by about 28,000 persons of the working classes; and buildings to accommodate 42 additional families are being erected in West

Kensington. The total expenditure on these estates will amount to about £1,103,000. The new blocks opened on Tuesday are lettered E E on our illustration, and have been called Moore Buildings as a compliment to the active and courteous secretary of the Company, to whose constant labour no small part of the success of the Company is due.

COMPETITIONS.

MAIDSTONE.—The town council have held a special meeting to decide the award for plans for the proposed technical institute. The competition was limited to architects practising in Maidstone, and only two plans were sent in, the mottoes being "South Kensington" and "Efficiency." The cost was limited to £6,500, with an additional £700 as provision for fittings, heating, and lighting. The institute will be placed near the existing museum buildings. The committee recommended that the design by "South Kensington" should be adopted, and this was agreed to. The author is Mr. Albert W. Smith, F.R.I.B.A., of the firm of Ruck, Son, and Smith, of Maidstone. Mr. H. Bensted sent in the design under motto "Efficiency."

NEWCASTLE-ON-TYNE.—The question of improving the accommodation and appearance of the Newcastle Town-hall was again discussed by the city council last week, when Mr. Baxter Ellis moved that the town-hall committee be authorised to expend not exceeding £350 in prizes for competitive plans by Newcastle architects showing the best method of improving the present town-hall buildings for the purposes of a town-hall and concert-room to meet the requirements of the city. Mr. Ellis declared that the concert-room was a disgrace to the city, and not fit to take ladies into, and that the exits and entrances were inadequate. A long discussion followed, and it was decided to reduce the amount to be offered in premiums from £350 to £100. This was carried, and a committee were advised to instruct Mr. Laws, the city engineer, to prepare a plan.

ST. PANCRAS.—The St. Pancras Vestry received on Wednesday deputations of ratepayers for and against the proposal to erect municipal buildings on a site already secured at the junction of Great College-street and King's-road with Pancras-road, opposite the Vestry Hall. The land was purchased at a cost of £6,500, and the estimated expense of erecting buildings is between £30,000 and £40,000. A petition signed by 590 ratepayers, including Messrs. Maple and other large manufacturers and shopkeepers, and representing a rateable value of £250,000, urged the erection of the proposed buildings in a more central, convenient, and commanding site than that suggested—namely, on land "somewhere between the Cobden statue and the Mother Red Cap Tavern," High-street, Camden Town. Mr. J. W. Dixon moved the adoption of instructions to architects with regard to the construction of municipal buildings on the Pancras-road site, and that architects be invited by advertisement to send in competitive designs for the new buildings, the premiums being 100, 50, and 25 guineas for the first, second, and third designs respectively. Mr. Bridgman proposed an amendment instructing the General Purposes Committee to "ascertain and report to the Vestry what sites there are in the locality between the Regent's Canal on the north and Euston-road on the south suitable for the erection of municipal buildings, with approximate estimates of the cost of the same." The original motion was, on a division, carried by 53 to 30; and an additional instruction was adopted requiring the competing architects to provide in their designs a hall at least as large as the hall in which the Vestry now met and let occasionally for public meetings, &c.

In connection with the reopening of St. Paul's Church, Knightsbridge, a new stained-glass window in memory of the Rev. the Hon. Robert Liddell, the late vicar, was dedicated on Sunday. The chancel has been extended by 15ft., and is intended to receive coloured decoration. An oak screen, carved in 15th-century style, separates the chancel from the nave. The screen was designed by Mr. G. F. Bodley, A.R.A., and is divided into five compartments. On the screen is a cross flanked by the figures of the Virgin and St. John. These figures were carved in Ober Ammergau. There is a new stone reredos. The Liddell memorial window represents the Tree of Jesse.

WAYSIDE NOTES.

THE "stones of Battersea" are in their way as renowned as the "Stones of Venice." Legends galore would seem to be gathering about them. Only the other day a correspondent of the *Standard* announced that these forlorn architectural fragments—that form, or formed some years ago, when I visited Battersea Park, a rare playground for *gamins* innumerable—"originally constituted the façade, or portico, of Northumberland House, Charing Cross." This is truly a startling announcement enough, seeing that most of us long laboured under the belief that the stones in question once formed part and parcel of the colonnade and gateway of old Burlington House.

In the face of such a statement, it is not surprising that another correspondent—"C. W."—hastens to prevent the establishment of a false tradition, and to point out that these "stones of Battersea" were advertised for sale in the year 1858, by the Government of the day, as "the admired stone erection of the colonnade and gateway at Burlington House," the said colonnade and gateway being designed in confessed imitation of the Palace of Count Vieriati, at Vicenza, and was pronounced by Sir William Chambers to be the finest thing of its kind in Europe. "C. W." says that in their present resting place the stones have become the subject of many conflicting traditions, "in the face of which," he moralises, with much pertinence, "it seems rather hard to flout the occasional differences of opinion entertained by students of the past with regard to the origin of Stonehenge."

These stones come into prominence with quite an astronomical periodicity. Now, someone complains of their decay and neglect; anon suggestions are made as to the reconstruction of the gateway and colonnade. Not so fortunate as the old stones of Temple Bar, they have been going to rack and ruin for long years, and from what I remember of their condition when I visited them, they have become so worn by weather, and so injured by the playful gambols of the *gamins* aforesaid, that they would be little use for the purposes of any reconstruction scheme. Were the stones in good condition, one would certainly advocate a restoration of the old gateway and colonnade at some park entrance or other not unsuitable position.

I have heard of "cut-and-come-again" and "cut-and-run," but never before of "cut-and-cover." If, however, I understand rightly the meaning of the expression in tunnel works, as used by the contractors for the Blackwall Tunnel, then the relinquishing of the method of working under compressed air will be more hazardous for the workmen in the drift. The compressed-air process practically insures safety from sudden "drownings-out." It is quite to be understood that the majority of workmen would be only too willing to abandon methods of working entailing more or less hindrances to speedy and easy operations, and doubtless working in compressed air is not so comfortable as labouring in an atmosphere at nature's own pressure. But the County Council, being anxious about men's wages, should, to be consistent, take even more thought for the safety of their lives, and, therefore, before allowing changes in the programme as set forth in the specification for the tunnel works, they should inquire into this matter. The referring back of the whole question on Tuesday last was, therefore, a judicious step, and will allow the Bridges Committee to proceed with due caution in permitting a change in the method of working.

Tuesday's meeting of the County Council was marked by a more than ordinary amount of attention to practical building matters. Subsequently to the consideration of the Blackwall Tunnel, the contract for the Barking-road Bridge was taken in hand, and the tender of the Thames Iron Works and Shipbuilding Company, Limited, accepted at £54,353, on the condition that the company pay the trade-union rate of wages. The Building Act Committee brought forward the matter of street hoardings, and recommended a low limit of height to be placed thereon—a recommendation with which we shall most of us agree. A new fire-brigade station being proposed for Queen's-road, New Cross, naturally

enough, a number of councillors thought this an excellent opportunity for the Council to commence building operations on its own account. Fortunately, a large majority saw the folly of deferring the erection of the new station until arrangements could be made for such a system of building, and sanctioned immediate continuance of the work of getting in tenders. Compared with the average meeting of the Council, the last one was remarkable for its despatch of business.

When speaking of the restoration of Rochester Cathedral last week, I should have said that Mr. Pearson would shortly be continuing the works at the cathedral, for works of restoration have now been going on there for a considerable time under Mr. Pearson's direction. I am told that some beautiful Norman diapering has been discovered and rebuilt into position, and that it is "worth anyone's while to make a special visit to see it."

I read of the new church of St. Philip, erected at the back of the London Hospital, and consecrated some few days back by the Bishop of Wakefield, that "no ornamentation appears on the exterior of the building." This promises well for the interior. Too often we find work lavished externally and stinted internally, whereas a building should so far bear analogy to a man that its great worth should be reserved and inward; and as a rugged exterior well covers a good heart, so plain and massive external façades are best suited to delicate and refined internal composition.

A correspondent writes:—"The past-masters at throwing mud are now flinging it at each other, and the organ of the R.I.B.A. howls and whines 'accordingly' at getting a touch of its own quality. Fancy 'deliberate misrepresentation' against its pets! Such was only allowable against the common enemy, and so the pot calls the kettle black, and the Education and Registration Bill advances a stage."

What a deal of cant continues with regard to the "craftsman"! It is time a few such took up the gauntlet, and said—what they could often say with truth—"Give us properly-trained bred-and-born architects to supervise, and we will turn out good architecture." There is a vast deal about this poor, unfortunate "craftsman" in the great work. He appears to be the root of all evil—such, at least, is the impression many will gather from a perusal of several of the essays.

Do a little more for the "craftsman," and he will then perhaps take more interest in the work he does for you. Spend a little of the 5 per cent. in charitable works on behalf of him and his kind; give a dinner or supper at the completion of every work of any importance, and let every man on the building, from hodman upwards, sit down to the fare, and do not think that your fine reputation and delicate architectural feelings will suffer by reason of yourself sitting at the table. Take an interest first in the workman and then in his work, and it is not in human nature to long remain indifferent to acts of kindness. Poor Sedding started this craftsman mania; but his arguments were founded on conviction and true feeling, while the cry of "Improve the craftsman!" has since developed into a sensational party slogan. Let us rather look to the improvement of ourselves; if need be, let more time be spent in demonstrating our ideas to workmen. It has always seemed to me that it is not the worker who is at fault, but the supervisor—the architect. Instead of allowing a carver or other worker to put some of his own ideas into a piece of work, he is bound down to every line and curve of a drawing or model. As a consequence, the executed work generally presents a hard, lifeless appearance. In the old days, to which those suffering from craftsmanphobia are so fond of referring, we have strong reasons for believing that, as a rule, the carver carved to his own fancy; and hence, feeling the joy of independent work and free and untrammelled thought, he, for very love of the labour, would throw every energy into the work in hand. Nowadays the architect has a grasping greediness for taking the credit for every square inch of design in the building.

GOTH.

Building Intelligence.

ABERDEEN.—The plan of building extension just adopted by the University Court is an important one, and is estimated to cost about £90,000. It comprises the extension and completion of the quadrangle at Marischal College by the extension of the north wing to accommodate the departments of chemistry, pathology, surgery, medicine, and law; the erection of a new front block facing Broad-street accommodating the administrative offices, University court-room, faculty room, committee room, secretaries' rooms, two sacristy houses, and lady students' rooms, also the departments of botany and agriculture; and the erection of a new graduation hall and students' rooms (the gift of Mr. Charles Mitchell, of Newcastle) in the rear of the present buildings, and connected with the existing hall and library and museum; likewise of the rearrangement and addition to the department of anatomy. The plan also provides for the erection at King's College of a new natural philosophy department and for students' rooms, including accommodation for ladies. The external appearance of the Marischal College buildings will be in character with the original design, the only change on the plan being that the hall is placed at the back in connection with the existing halls instead of in the front block, which is now to be devoted to administrative offices, botany, and agriculture. The architect is Mr. Mackenzie, of Messrs. Matthews and Mackenzie, Aberdeen.

CRAWSHAWBOOTH.—The new church of St. John the Evangelist at Crawshawbooth, near Goodshaw, in the Rosendale Valley, was consecrated by the Bishop of Manchester last week. It is in the Late Decorated style, and is built of local stone, with Yorkshire stone dressings. A tower 23ft. square, and measuring 95ft. from the ground to the top of the parapet, and having pinnacles running 27ft. above the parapet, thus giving a total height of 122ft., is now the most striking landmark in the locality. Internally the church consists of a nave, 80ft. by 24ft., of five bays, and there is a chancel, with a roof of polygonal form, some 50ft. by 24ft. The east window of the chancel has six lights, and the west window five lights. Accommodation is provided for about 600 worshippers, and the total cost of the building and furnishing is put at about £12,000. The lower part of the tower forms a commodious organ-chamber, and opens into the church by two lofty moulded and panelled arches, 25ft. high. A north chapel or organ-chamber of one bay, carried up to the full height of the nave, adjoins the east side of the tower. The church is lined internally with red Rainhill stone, the chancel being of face-dressed ashlar. The passages are flagged, and the floor under the seats is laid with wood blocks. The chancel pavement is of tiles and stones.

SOUTHPORT.—The foundation-stone of the new infirmary was laid on Thursday in last week. The site is five acres in extent, and is bounded on three sides by streets, the main frontage extending 121 yards. The width of the building will be 243ft. The style is a Free treatment of Flemish, the external walls being of red stock bricks, relieved with Longridge stone dressings and a small quantity of terracotta, with roofs of Westmoreland slates and red ridgings. The central portion of the main frontage will be two stories in height, while the ends and corridors will be only one. In the centre of the front block there will be an octagonal brick and stone clock tower, surmounted by a wood and lead lantern, rising to a height of 76ft. One of the main features will be the central arrangement of the out-patients' department, which will easily accommodate 70 persons. From the centre of the main corridor, running towards the back of the building, is a corridor 9ft. wide, leading to the accident ward and the operating-room. The isolation ward block is a distinct hospital in itself, having ward nurses' room, two wards for two beds each, baths, lavatories, and linen-rooms. Gardens surround the whole buildings, those to the front being laid out in a circular form, with a fountain in the centre. Mr. C. Sydney Ingram, of Manchester and Southport, is the architect; the contracts for building are not yet let.

The Peel Mill No. 2 at Bury, Lancs, will be formally opened to-morrow (Saturday). Messrs. Stott and Sons, of Oldham, were the architects.

THE "RENDU" OF ARCHITECTURAL DRAWINGS.—II.*

IN order to effectively render or colour a geometrical drawing, all the effects explained in the last article should be taken into account. The direct, the reflected rays, effects of distance, contrast and irradiation should carefully be observed whilst colouring; after a while the eye and hand will combine in naturally producing the desired result.

The colour should be used sparingly and with good taste, and vulgar effects should be avoided. The harmony of light and shade and distance is obtained by means of the science of colouring, combined with method and artistic feeling. The shadows should be carefully put in, and the colours laid on in light flat or graduated washes, the effective touches artistically indicated. Often when clearness of effect is necessary only, the shadows may be indicated, and a simple wash of general colour put on, with a few touches of lighter or darker colour; the building will then appear to stand out from the paper with all the effect of light and shade.

One of the most important things is the ability to well model in colour and shadow rounded surfaces, such as columns, towers, &c. This is not easy at first, the young beginner often spoiling his drawing and temper over the modelling of a rounded surface, and utterly failing to get the proper effect. This is because he does not understand the principle of shading, the exact points at which the direct light strikes the surface, and the points where colour or shadow is necessary.

Therefore, before proceeding to explain the tinting of an ordinary flat surface, we will consider the modelling of a rounded body, and the rules for obtaining the desired effect. In the last article we spoke of the effects of light and shade on polished and unpolished surfaces. As a rule, in architectural drawings we have to occupy ourselves only with unpolished surfaces, such as stone, wood, &c., in their natural state—that is so say, surfaces which reflect the light in a diffused state, as explained in the last article. In a circular body we have three principal effects of lighting to take into account. When a surface is well lighted, a certain proportion of the rays of light are absorbed, and a certain quantity reflected, and if the light is not too intense, and a fixed proportion of the rays are absorbed, the reflected rays will take the apparent colour of the object, which will itself appear tinted with its local or natural colour. If, however, the lighting becomes more intense, the reflected rays become charged with the superabundant white rays, the local colour disappears, and the tint appears lighter in colour, and almost white. But if, as in the third case, the amount of lighting is lessened, all the rays are absorbed, and the local colour assumes a darker tone, mingled with shadow.

The rays of light coming at 45° strike the surface in full at y , Fig. 5, and at a tangent at z . The point y is therefore most brilliantly lighted, the point z almost in shadow, and the intermediate point x more or less lighted. This point x therefore being lighted moderately, and absorbing all the white rays, reflecting only the coloured rays, will appear in its natural or local colour; the point y brilliantly lighted, and sending back the white rays which are not absorbed, will appear lacking the local colour, and almost white; and the point z very little lighted, and absorbing all the rays of light, will appear with the local colour mixed with shadow. Between these three points the lighting is graduated, that from x to y gradually weakening in colour, and from x to z gradually deepening in colour, mixed with shadow.

Now, in order to determine the scale of tints necessary for modelling a rounded surface, we have first to find the scale of light and shade, by means of a perfectly-constituted surface, that of a sphere. We need not enter into the method of finding the lines of the sphere, Fig. 6. This sphere is intersected by seven planes, equidistant from each other, parallel to each other, and perpendicular to the direction of the rays of light. The surface is thus divided into a certain number of zones, 1, 2, 3, &c., and—1, 2, 3, &c., starting from the line o , which corresponds to the point z in Fig. 5. Of these zones the most important are x , y , and z . Zone z is that coming directly after the line o , separating the lighted portion from that in natural colour; x , that which, receiving the ray of light in a certain degree,

appears tinted in local colour; and zone y , the portion of the surface brilliantly lighted, and therefore light in tint. Thus if the sphere

were coloured red, the zone x would appear tinted with all the force of the red, the zone y almost white, mixed with a little red, and the zone z the local colour, mixed with a certain amount of shadow colour. The intervening zones connect these by means of graduated tones. We are therefore able, by means of this sphere, to establish a fixed scale of lines of tints for rounded surfaces. It is evident that if we wish to find

the lines of tints for modelling a vertical cylinder, such as a column, &c., of the same diameter as the sphere, by circumscribing the surface of this cylinder to the horizontal circumference of the sphere, and marking off the points from this circumference on the surface of the cylinder, we obtain the lines of tints for the cylinder. The line A B, Fig. 6, forms, therefore, a fixed scale of lines of tints.

In Fig. 5 we have a portion of a column, A C, of any given diameter; by means of the fixed scale A B and lines parallel to B C from the points 1, 2, 3, &c., we mark off the corresponding

points on the line A C, and raise the verticals therefrom. On looking at the plan we see that these points are correct; the line of natural shadow o is the projection of the tangent point z , the intermediate point x falls in the zone from 4 to 5, and the well-lighted point y in the zone 6 6.

In Fig. 7 we have the same cylinder capped by an abacus, and in natural shadow from d to e , in cast shadow a, b, c, d . We will follow the method for modelling the surface. The lines of tints should be marked very faintly in pencil in the lighted portion, more forcibly when under the cast shadow, and very firmly in the portion in natural shadow.

Let us first model the cylinder in Fig. 7 by means of a series of flat washes in Indian ink or sepia. We must mix a tint of a certain degree of intensity, say two-thirds, in the scale of white and black, and pass it over the whole portion in shadow. A little water is then added to the colour, and this lighter tint is passed over the zones 1 to —1, and over the whole portion in shadow to the left of —1. A still slightly lighter tint is then to be passed over the portion 2 to —2, and the whole portion in shadow to the left of —2; a still lighter tint from 3 to —3, &c., and so on, until six successive tints have been passed over the surface in light and shadow. The surface should now appear rounded, but the portion in cast shadow is not yet sufficiently modelled. A very dark tint should be passed over the whole zone 6 6 in shadow, a slightly lighter from 5 to 5, and so on, until six tints have been put on, stopping at tint o with a tint very slightly darker than the original tint put on at the commencement of colouring. The cylinder in shadow should now appear well modelled.

Naturally, the method of modelling with flat tints is long and tedious; but the student should practise this at first before attempting modelling by means of graduated tints of colour. Let us now model the same cylinder by this second process. The original dark tint is, as before, washed over the whole portion in shadow. The zone y , being well lighted, we have to leave nearly white, so with the brush full of water we wet the zone y ; then, quickly adding a little colour, we graduate the tint rapidly to the left, and again, before the zone y becomes dry, repeat the same process to the right, gradually adding more colour until the tint is brought at its brightest to the line o , and from this line graduated over the remaining portion, d, e , in natural shadow, softening the tone as the exterior line is approached. Then we cover the zones 6 and 5 with pure water, and adding gradually more and more shadow tint, reach the line o , and from thence to the exterior line, softening the tone. The modelling in colour and half-tints is now completed; it remains for us to finish the cast shadow a, b, c, d . We pass a wash of shadow tint slightly tinged with the colour of the object over the portion in cast shadow only, commencing at line o , and gradually darkening the shadow as we approach the zone 6 6, which should be the portion in deepest shadow.

The sphere may be modelled in a similar manner. With the brush full of water slightly tinged with the colour given to the sphere we cover the whole of the zone y (Fig. 6); then, gradually adding colour, we bring the wash to the zone x , when the tint should be at its brightest, and from this zone we bring the tint, without adding more colour, over the remaining surface. Then the whole of the surface in natural shadow must be covered with shadow tint. Again commencing with pure water at zone x , and gradually adding shadow tint, we cover the zones 5, 4, 3, 2, 1, and graduate the wash on the remaining zones in shadow.

The student should practise modelling to a large scale a number of spheres and cylinders. Of course, after a while, the scale of zones may be dispensed with, the eye becoming experienced in the right proportion to be given. He must, however, remember that the whole effect depends on the exactness of the positions of the principal zones x, y , and z , the points of brilliant lighting, local colour, and shadow.

ARTHUR VYE PARMINTER.

BOOKS RECEIVED.

Advanced Building Construction—a Manual for Students, by the Author of "Notes on Building Construction" (London: Longmans, Green, and Co.)—is a reduced edition of Part II. of "Notes on Building Construction" intended for students

in the second stage or advanced course of this study, held under the direction of the Science and Art Department. Certain portions of the "Notes" as first published are omitted as not required at this stage, and the resulting volume is smaller and more handy, illustrated by the same diagrams, and printed in clear type. As one of the Advanced Science Manuals published by Messrs. Longmans, Green, and Co., we can highly recommend it to all students of building construction. The subject of stresses on structures required by the syllabus is dealt with and illustrated by diagrams of beams differently loaded. The student will find how concentrated and uniformly distributed, or partially distributed, loads act, and the nature of stresses under varying loads and supports. Materials, including bricks, stone, limes and cement, timber, iron, and steel are succinctly treated, and the detailed information, as varieties and tests, are printed in smaller type following the arrangement in the Notes. We know of no better or more concise elementary statement of the properties of limes and cements, plasters, or timber. The chapters on the several branches of construction are well arranged and admirably illustrated, as in bond, arches, chimneys of brick. The sections treating on timber roofs and coverings comprise much useful information as to construction, slate, tile, and zinc laying. Wrought-iron girders, iron roofs, and fireproof floors are thoroughly explained and illustrated by details clearly drawn and figured, and in these respects the Manual is certainly superior to the treatment found in other elementary handbooks on construction.—MR. JOHN HOLLINGSHEAD tells in a well-illustrated shilling volume just to hand *The Story of Leicester Square* in a very readable and entertaining fashion. From the immense mass of trustworthy material available for collecting facts as to the history of the square during the past four or five centuries, Mr. Hollingshead has compiled a pleasant narrative in which figure such varied claimants to fame as Lawrence, Hogarth, and Reynolds; Peter the Great and George the First; Chippendale the cabinet maker, Dibdin, Edmund Kean and Ben Webster, E. T. Smith and the Farinis, Hunter, Bell, and Cruikshank. We have references to the Alhambra and Empire, and the many shows that have been held in or near the "square of squares." A chatty letter by Baron Grant tells us how that once famous financier came to purchase the freehold of the square, to transform the inclosure from a filthy wilderness into a blooming garden, and to present it to the Metropolitan Board of Works. Messrs. Simpkin, Marshall, Hamilton, and Kent are the publishers.—*The Ornamental Draughtsman and Designer*, by several practical draughtsmen and designers, arranged by Robert Scott Burn, editor of "Illustrated Drawing Book," the "Building and Machine Draughtsman," &c., with folding plates and illustrations (London: Ward, Lock, Bowden, and Co.), is a series of practical instructions illustrated by examples of freehand drawing in outline and from the round, of styles of ornament. Those handbooks, forming the "Practical Mechanic" series, are useful to all who wish to acquire the rudiments of technical knowledge, and the present volume follows on the lines of the "Building and Machine Draughtsman," "General Machinist," and other books of the series in the fulness of the illustrations and the explanatory remarks. The instructions given for drawing, rectilinear and curved lines, and ornament and on shading, will be found of service to all mechanics, artisans, and apprentices in the engineering and building trades, and the remarks on form and colour contain much useful advice to this class of students.—*The Grammar of Woodwork: A Graded System of Manual Training for Elementary, Secondary, and Technical Schools*. By WALTER E. DEGERDON, Head Instructor in Woodwork at the White-chapel Craft School (London: Macmillan and Co.)—This is a series of lessons on the elements of the use of woodworking tools, designed for the pupils of the above school, over which Mr. Degerdon is master, and it is thought they might be useful to a wider circle of students. The value of manual training as a part of a general education is admitted by all. The author's lessons are graduated by easy steps. The earlier lessons consist simply in using tools to true up, square, and make to a certain length, width, and thickness a piece of wood; then follow exercises in planing to given dimensions, chamfering, making prisms, cutting shoulders, sawing and boring with brace and bit; in chiselling, rebating,

inlaying, setting-out, mouldings, mortising, parquet-work, and other more complex operations. Plans and elevations and isometrical drawings illustrate each exercise, and these are clearly drawn to a scale of half an inch to the inch, or half full size. Each separate operation is explained under a separate heading, which is a great aid to the pupil, and there are 21 lessons in all. We should have preferred to see a few more constructional or practical problems introduced, such as framing and simple joiner's work; but this system is not recommended by Mr. Degerdon, whose exercises are simply intended to train the hand in the use of ordinary woodworking tools to the satisfaction of the eye already trained in drawing. Tulip wood is recommended as a clean and sound wood for the models. Real trade teaching is avoided in the system here recommended, and we think for elementary schools the principle is the right one. It would be injurious to those apprenticed to the trades to have to compete against young men who had only imperfectly learned the elements of carpentry and joinery, and therefore the attempt to teach trades has been generally objected to. We can cordially recommend Mr. Degerdon's exercises in woodwork.—*The Iron and Steel Maker*, by various practical writers, edited by F. JOYNSON, with plates and illustrations (London: Ward, Lock, Bowden, and Co.), is a useful compilation, containing detailed descriptions of the various processes for the conversion of iron ores into pig or cast iron, wrought iron, and steel, with illustrations of the furnaces and appliances. The student desirous of mastering the processes of ore conversion, of iron and steel manufacture, the great revolutions effected by the discoveries of Bessemer and Siemens in mild steel-making, and the "open hearth" process will find this book a good introduction. A sketch is given of the early history of iron manufacture, the system of making iron with coal as a fuel, the smelting of iron ore, the blast furnace, the different regions of the reduction of the ores in the furnace, its action, the chemical changes, the appliances and machinery puddling furnaces, cast iron. Steel, making is next discussed; the early methods are fully described, afterwards those methods which have commenced a new era in steel-making, that associated with the invention of Sir Henry Bessemer.—*Lectures on Sanitary Plumbing, &c.* (Manchester: John Heywood).—The Manchester Council of the National Registration of Plumbers are issuing a series of penny pamphlets containing lectures on "Sanitary Plumbing," by experts, which cannot fail to be of value to all plumbers and their employers. Amongst the lectures to hand is an introductory address by Mr. John Holden, F.R.I.B.A., the president of the Council, prefixed to a lecture on "Domestic Hot-Water Supply and Fittings," by Mr. Joseph Corbett, sanitary engineer, in which the principles of hot-water heating for houses are explained and illustrated by diagrams; "Reasons why Sanitary Authorities should Employ Qualified Plumbers as Sanitary Inspectors," by Mr. M. Ingram, Mem. San. Inst., vice-chairman; "Electricity in its Relation to Plumbing," by W. W. Haldane Gee, B.Sc., &c.; "Sewer Gas, and the Methods of Dealing with it," by J. Radcliffe, F.R.M.S.; "How to Elevate the Status of Plumbers," by John Allison, M.Inst.C.E., City Surveyor; "Domestic Cold-Water Fittings," by Mr. Joseph Corbett, sanitary engineer, &c. These short lectures contain many useful suggestions.—*Manual of Continuation Schools and Technical Instruction*.—By CHARLES HENRY WYATT, Clerk of the Manchester School Board, &c., Illustrated (Manchester: John Heywood). The volume will be found of service to authorities who are charged with the provision of continuation schools and those for technical instruction. Under the new Code of 1891 various branches of commercial and technical instruction call for the establishment of schools and classes in all parts of the country. For all promoters of Elementary Evening Schools and technical schools and classes and higher grade schools this work will be of practical value, and the plans given of the Higher Grade School are useful. They are arranged on an economical principle, with separate floors for boys and girls. Much useful and statistical information will be found in Mr. Wyatt's book, which should be in the hands of every schoolmaster and teacher.—*Lightning Conductors and Lightning Guards: a Treatise on the Protection of Buildings, &c., from Damage*, by OLIVER J. LODGE, D.Sc., F.R.S., LL.D., &c. (London: Whittaker and

Co.), forms one of the Specialist Series of volumes published by this firm. Dr. Lodge's manual is a very complete handbook, the outcome, we are told, of a couple of lectures which he delivered at the request of Sir Trueman Wood, at the Society of Arts. The author exposes many of the current ideas as unfounded, and as not verified by experiment, the fact being that the momentum of an electric current has not been taken into account, and the old "drain-pipe idea" of conveying electricity gently from cloud to earth has been proved to be wrong. From the conclusions of this authority it was thought that lightning-rods were unnecessary, but the author says they are "essential to anything like security, notwithstanding the freaks of lightning strokes." But the system of metallic protection now advised is that known as the "cage system," in which wires are carried along all the prominent portions of a building. We recommend Dr. Lodge's work to the attention of all architects.—*Charing Cross to St. Paul's*. Notes by JUSTIN MCCARTHY, M.P., and vignettes by JOSEPH PENNELL (London: Seeley and Co., Limited), has already appeared in the *Portfolio*, but will be welcomed in this form by all who have already seen it. Mr. Pennell's pictures and Mr. Justin McCarthy's chatty paragraphs go well together. By the way, the former should have taken our bit of the Strand, as we are shortly to disappear before the ravaging tooth of the London County Council. It is a little hard that twice in a decade we should have to change offices in obedience to the march of improvement. The Duke of Bedford turned us out to make room for Covent Garden Market extension, and now it seems likely our place and habitation are to be lost in the wide opening that is to be made into the Strand by "the Council Broadway."

CHIPS.

The opening meeting of the Royal Institute of British Architects will be held on Monday evening next, when the inaugural address of the session will be delivered by the President, Mr. MacVicar Anderson. The next public meeting of the R.I.B.A. will be four weeks later, Dec. 5th, when several papers on "The Sanitation of Cities" will be read.

The late Baroness Taunton has bequeathed to the National Gallery a picture of the Holy Women at the Sepulchre, by Mantegna.

The stained-glass window which has been placed at the west end of Aylesford Church, in memory of the late Mr. H. A. Brassey, J.P., was formally presented on Friday. The work has been carried out by Messrs. Burlison and Grylls, of London. Our Lord, St. Peter, and St. Andrew are represented, and at the bottom of each figure there are representations of acts of mercy and charity. At the top of the window, which is a three-light one, are placed the arms of the Brassey family, and also the arms of the county. The mason's work has been carried out by Messrs. Wallis and Sons, of Maidstone.

The marriage took place on the 27th ult. of Mr. Edmund Woodthorpe, vice-president of the Architectural Association, of Grayshotts, Hants, and Circus-place, E.C., to Annie Kate, eldest daughter of Benjamin Warner, of Wanstead and Newgate-street, E.C.

The corporation of St. Helen's, Lancs, have adopted plans by Mr. Brown, their borough surveyor, for an extension of the fever hospital at Peasley Cross, so as to accommodate 24 extra beds. The estimated cost is £2,500.

The new public rooms at Bodmin were opened last week by Mr. Courtney, M.P. The large hall is 80ft. by 40ft., has an open-timbered roof, and is seated for 800 people; the smaller hall is 35ft. by 20ft. The architects are Messrs. Octavius Ralling and Lewis Tonar, of Exeter, whose design was obtained in competition among the architects of Devon and Cornwall. The work has been carried out by Mr. Sampson Trehane, of Liskeard, under the supervision of Mr. M. Oliver, clerk of works. The cost has been £3,500.

The new workhouse infirmary for the Guardians of the Dawsbury Union, which is being erected at Staincliffe, is nearing completion. The work is being carried out from the plans and under the supervision of Messrs. Holtom and Fox, architects, of Dawsbury. The whole of the large wards are warmed and ventilated by means of Shorland's double-fronted patent Manchester stoves, with descending smoke flues, and in the smaller wards and day-rooms single-fronted patent Manchester stoves are used. There are some thirty of these Manchester stoves used in all, the whole being supplied by Mr. E. H. Shorland, of Manchester.

Correspondence.

WALSALL PUBLIC BATHS COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—My attention has been called to an effusion in your issue of 21st inst., emanating from one who subscribes himself "Disgusted Competitor," and who informs you that from the account he read of the above, he gathered the following—viz., that:—

1. "Two of the three premiated designs will not go on the land, the first encroaching on the land reserved by the Council for the erection of shops."
2. "Neither the first nor second designs has separate entrances to the female slipper-baths."
3. "There is only one entrance to Design No. 1, over which coals and everything have to be taken."

4. "No provision for replacing the boilers is made. I have heard it said that if this plan (No. 1) is carried out, and anything goes wrong with the boilers, the baths will have to be pulled down to take in a new boiler."

Now, although such absurd misstatements might be treated with the contempt they deserve, I having been for the last twenty-five years intimately connected with the designing and construction of public baths, and the designer of No. 1, think it only fair to your readers and

SIR,—The statements in my letter in your issue of the 21st ult. were obtained from the Walsall papers of the 15th ult. I would recommend the competitors in the above competition to get either the *Observer*, *Free Press*, or *Advertiser*: they will then be able to form an opinion as to the accuracy of my statements and the merit of the selected designs.—I am, &c.,
Walsall. DISGUSTED COMPETITOR.

SIR,—In the instructions issued for the above it is distinctly stated that "any architect revealing his incognito intended to be preserved by the 'motto' to be adopted by him will be disqualified for selection." Yet in the face of this definite clause, is it a fact that the author of the design placed first, though not directly disclosing his name, yet went so far as to say that he had erected the baths at Camberwell?

Surely this amounts to the same thing, and should have been enough to disqualify him. Yet he was placed first. It shows that the statement biased the committee, for one of the councillors referred to it in the discussion by saying he would rather trust one who had erected baths than a novice.

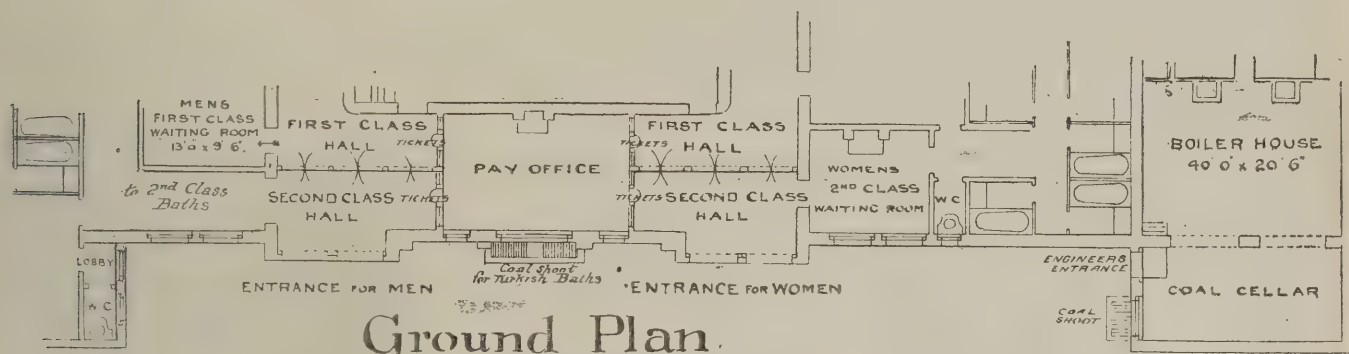

That there was considerable difference of opinion in the council with regard to the committee's recommendation is evidenced by another councillor, who moved an amendment that a professional assessor should be called in, saying

the error at 40 links, and (as the proportion of alteration varies as the error changes) to compare the two results and say that I said 5.5 was half of 24, if it is not wilful misrepresentation, is due to want of knowledge of the method used. As I stated in my last letter, when I thought that "Northman" did not quite understand the method, I took his exact figures in my letter in your issue of September 23. Surely he would do better to argue about these exact figures than to make himself ridiculous by arguing about a method he obviously fails to comprehend.

With regard to Fig. 4, it makes a considerable difference whether B C is measured from B to C or from C to B (the direction of scaling off the drawing, of course, makes no difference).

I. Measuring from B to C. If the position of D is counted 40 links out, A F will show the error by an alteration of 22 links, as I stated in my letter in your issue of September 23. If an error were committed by dropping one arrow in exchange between B and D (if the distance was long enough), the whole length B C would be altered, A F would show no alteration, and E D would be the check on my diagram. The error could not be less than one chain, and E D would show it clearly.

II. Measuring from C to B. A F will not show any error committed. In this case E D is the check on my diagram, although, as set out, not intended to show errors so small. Then E B would be a better check; but the question

Ground Plan.

myself that I should have an opportunity of refuting them, and this I feel sure, you Sir, with your usual fairness, will allow me to do so. I will therefore take them seriatim:—

1. No. 1 design, instead of encroaching on the reserved land, is in strict accordance with the limits laid down as to setting back.

2. It has separate and distinct entrances, both for the men and women's slipper baths.

3. Besides having separate entrances for men and women, it has also an engineer's entrance at side and two coal-shoots—one for supply of Turkish baths, and the other for the boilers.

4. In my design, the boilers are placed in a shed at the side of the main building, and could be removed and replaced at any time without disturbing any part of the main structure.

Should "Disgusted Competitor" desire it, I will instruct him, not only how to get a boiler out, but also how to set one.

The above facts will, I think, be sufficient to enlighten your readers (unless they all happen to be "disgusted competitors") as to the manner in which your correspondent (because unsuccessful) has endeavoured to depreciate the designs of his more fortunate brethren. Why does he not give his name, and let us see his design? It would, no doubt, be interesting also to know where he derived the information on which he bases his strictures. From what he says, he has evidently not seen the plans, and only obtained his information from newspaper reports or from hearsay.

Might I suggest to your correspondent, whoever he is, that, when next he takes upon himself to criticise designs which he has not even seen, he should at least be sure that the information "he gathers" is correct?—or otherwise I fear that if his designs are in accordance with his facts, he will never sign himself anything but a "Disgusted Competitor."

I inclose you a tracing showing the arrangement of the entrances and pay-office and boiler-shed in my designs.—I am, &c.,

HORACE T. BONNER, A.R.I.B.A.

that if the boilers as shown on the selected design burst, they could not be removed after once being fixed in the positions shown.

Another councillor pointed out that the Turkish baths as shown could not be ventilated, and objected to the positions of the closets.

The design placed third had the following points, which I suppose specially recommended it for selection:—Size of dressing boxes 2ft. by 1ft. 3in., 1st and 2nd class entrances, but the classes intermixed. No waiting-rooms, and the entrance through a road 9ft. 6in. wide, encroaching 3ft. on to adjoining land.

The 2nd and 3rd premiums were, however, awarded to Walsall men. This perhaps explains the selection.

The second design also has dressing boxes 2ft. by 1ft. 3in. It seems to me a great pity that the town council invited professional gentlemen to waste their time in sending in designs if they did not mean to deal with the matter in a perfectly fair and straightforward manner, and although I do not suppose it would have much effect, I would suggest that every competitor who fully complied with the instructions should sign a memorial protesting against the way this competition has been decided. I hope, for the credit of the town council, there was no wire-pulling; but the significant remark of one councillor who would not vote, and gave as a reason that he saw "so much fingering on the subject," almost compels one to come to the conclusion that all was not fair and above board.—I am, &c.,

ANOTHER COMPETITOR.

LAND SURVEYING.

SIR,—With regard to Fig 5, I have already answered "Northman's" letter of Oct. 7 completely. All I can do is to repeat my answer in different words in the hope that I may thus make it clear to him. The method I used (which for convenience I have called the "approximate method") depends on the premise that the error is infinitesimal, in which case the figures I have given are (approximately) correct. "Northman" took

whether E D is sufficient is one of opinion, and in matters of opinion authorities are the only guide. I wished to show that experienced and reliable authorities have considered such a check sufficient, and the statement by "Northman" in your issue of Oct. 7, that his check is the correct one, is a most unwarrantable statement. In the way he has measured, it is more accurate than E D, but it is not correct.—I am, &c.,

Gravesend, Nov. 2.

G. W. COBHAM.

A SLUMBERING INSTINCT.

SIR,—One of the many directions of modern advancement seems markedly to be the substitution of conscious mental effort for the far humbler and unconscious effort of instinct. We are more and more moved by an eminently complex intellectual appeal, and less and less by unreasoning, though in itself more decisive, instinct. Our instincts are invariably influenced, and most often fettered, by our reason. The sense of propriety is the all-governing sense, propriety of thought as of the realisation of thought. We dare not trust our instinct—if we, by chance, ever have it—unless, as is rarely the case, our hard, shrewd intellect supports it in every direction it may tend. We like to be charitable: Intellect whispers, Beware of imposition. We found a society and fasten up our purses. We love: Intellect insinuates, Is it prudent? We stick to the counting-house and go, for distraction, to the Alhambra. We feel we can design: Intellect says we must be properly instructed. We pass our grade at South Kensington and—we design. Method of reason must govern the waywardness of instinct. Our faculties of inward perception are numbed and of nought; the antinomies of pure reason give us infinite joy, and we have built, and live in, Belgravia and South Kensington.

Yet there is room in us for both reason and instinct: neither should be disparaged, and neither can be set at nought. Our faculties, both perceptive and receptive, should be suffi-

ciently enlarged to value both at their true worth. The human soul, as has been well said, is hospitable and capable of giving entertainment to conflicting sentiments with the utmost impartiality. Let us be but impartial in our hospitality, and award as good lodging to what we feel to be right as to what we think we know to be right, and instinct would be reborn to the world's advantage. But for our partiality, scholasticism would never have usurped the place properly belonging to the wider range of instinct. The age would have been more inwardly and outwardly appreciative; there would have been more real beauty in our lives and habits, and, perhaps, less talk of it; a quicker acknowledgment of the necessity of beauty in little things as in great, since the great things, after all, are made up of little; commercialism assuredly would have been the servant rather than the mistress of art.

It is to this practical advantage of the awakening of a certain instinct—that of the beautiful in all things—that I would now more particularly point. There can be no particular cause why this instinct should be divorced from reason and reason's god, Commercialism; but there is every reason why the two, for their mutual benefit, should be united. They are not in themselves antagonistic. That they can be and have been united is proved by the truthful record of the world's art. In our country alone, the placing as much as the designing of our cathedrals, the grouping of our villages, the making of our roads and lanes, the cottage furniture, the cottage garden, the almshouses, manor-houses, and homesteads prove the undoubted existence of some mighty instinct for beauty in its purest and most significant sense, for which we were richer then and are poorer now. In the stricter domain of pure commercial utility, witness the effort which beauty makes to the present day in the utensils in common use in the smaller Italian towns, such as the water jars of Ancona or Bari, in which we may detect a careless instinct for the admirable in outline as in workmanship and material, which is all the more fascinating because it is careless, and obviously the result of accident rather than of pre-meditated design. Yet now this feeling of the needfulness of some sort of beauty in all around us is absent. We take all that is given us, no matter in what form, and are thankful. We praise God and the manufacturer, for both are omnipotent. In little, as in great things, our reason dominates our instinct. A bowl is to hold water: what can be better or more suitable than an American bowl of glazed paper intended to represent granite? What can be more beautiful than a zinc bath made to represent marble inside and oak outside, or a bent wood chair or mosaic linoleum, or anything and everything that the manufacturer produces in his ignorance of reason for our use and in sheer, wanton defiance of our instincts? If there is any method in all this, and reason is method no less than is a governing perception, it is simply a method which has for its aim the promotion of unloveliness, and this is an attribute one would wish not to ascribe to the power of intelligence which rules the world. We are careless of beauty, and the keen manufacturer accurately gauges our powers of resistance. He thinks in his wisdom and counting-house that the instinct for consideration in all matters of design, which once was ever present, is now dead and gone; it is for us to prove that it can be recalled to life.

No one would blame the manufacturing producer for all this. He is simply a product of a reasoning age—an age that counts utility more than beauty, and cannot see that both are of equal value, or why utility should not be invariably appraised in shoddy. The much-abused and oftentimes maligned manufacturer is really our *alter ego*—or our Frankenstein. He is what we ourselves make him. We are indifferent, and so he becomes indifferent also. The worst of it is that our indifference, in the first place, is a negative quality; the manufacturer's indifference speedily becomes a positive quality working invariably in the direction of ugliness. The rankest growths are the strongest when tended by neglect. A harmless necessary stove and fender, under a stimulating course of indifference, speedily become overlaid with ornamental excrescences, whose designer, were we charitable, should be mentioned in our prayers. The genius of Curtain-road makes sport of us; picture-dealers give tone to and rule the market—it surely cannot be long before we have a fully-recognised,

open picture-exchange, and the ruling prices quoted day by day in the money articles of the papers—fashion and “this season's goods” are firmly-rooted in all the wide domain of decorative art, and unfortunately we get both novelty and fashion whether we desire them or not. Yet it cannot be doubted that were our right instinct aroused, we should not delegate our responsibilities to the unchosen few, and we should in consequence be richer in all those countless beauties of life which are now the sole definition of wealth.

We have no right to assume a wealth we do not possess. Our reason seems to be perfectly satisfied with things as they are. Our instinct, if we would but allow its influence to be felt, is certainly dissatisfied. And until reason admits that instinct is a power to be reckoned with, we shall jog along as we are without change. And reason can only be influenced by something as great as itself. Let us admit that, and awaken our innate perception of the beautiful, which, in this connection, I like to think is, without the additional power of any personal genius, a universal instinct; for then and then alone will reason meet its match and be compelled, in its own interests, to acquiesce in a partnership which should never have been dissolved. Art will be the richer for its universal acknowledgment as a necessity of being; the manufacturer should be no poorer; the conditions of labour would be rendered more interesting and bearable; and we, the purpose of all manufacture, would have the additional satisfaction of knowing that by our effort alone the change was wrought, and would enjoy the subtle pleasure of our very own labour.

The power to effect this is in us all, but now it slumbers.—I am, &c., LEWEN SHARP.

Intercommunication.

QUESTIONS.

[10878].—New Lights in Old Boundary Wall.—Has an adjoining owner legally a right to break out new windows in an old wall (which forms the boundary)

where none have ever existed before, and which immediately overlook his neighbour's living and bedrooms, about 8 ft. distant? Also, if a high fence, wall, or a building could be erected in the 8 ft. space, which would completely block the new windows?—LEGAL.

[10879].—Stucco Front.—I am repairing an old house having a painted stucco front, which is not worth repainting, and I want to know if there is any binder which, if put into water colour, would make same adhere to painted surface?—S. A.

[10880].—Fireproof Floors.—Can any reader inform me—without partaking of the nature of an advertisement—what are the best systems of fireproof or fire-resisting floors now in use for domestic buildings of the better class? It appears probable that the London County Council and the municipal authorities of our larger towns will, in course of time, put a limit upon the use of wood in floors of buildings where they have control, and it is very desirable to know what are the advantages of special systems, and if there is any plan more economical than the better-known patented methods of fireproof floor construction, and which would do equally as well for ordinary buildings?—VIATOR.

[10881].—Severn Tunnel.—Can anyone inform me what sort of brick the arching of the Severn tunnel is executed in? Also, whether there are pumping stations in the tunnel?—DOUBTFUL.

[10882].—Water Pipes.—I shall be much obliged if some of your readers will tell me, through the medium of your paper, what are the best descriptions of pipes to adopt in a house where the water is so soft that it acts upon lead?—INQUIRER.

REPLIES.

[10833].—Timber and its Position.—I am very sorry for suggesting to “E. S.” that he should read some authorities on the growth of timber, when it appears he did so half-a-century ago. However, if he will look through pages 362, 363, and 364, of Rivington's “Building Construction,” Vol. III., he will find the names of the woods which show the most clearly the sap valves or pores. I give sectional sketch of an ash-free stump taken on the spot, which had been felled but a short time. The annual rings are considerably enlarged, so as to show the sap-valves more plainly; but they are quite distinct in

the stump. To see the section clearly it is necessary to cut the stump with some sharp instrument, such as an axe, and not with a saw, as is generally the case with

balks of timber found in a timber merchant's yard.—SIDNEY F. HARRIS.

[10852].—Tidal River Bath.—I must thank “Tidal Wave” for his sketch, which shows the case to be rather more complicated than appeared at first, and still, I think, lacks some necessary information. The sketch seems to show that the pipe is to be laid level, and that the dimension 4 ft. is from top of coping of filter wall to H.W. level. What is depth of filter? How far and to what level does bottom of bath slope up? There is an error either in the capacity of bath as given in query of Sept. 16, or its dimensions given in sketch, as a bath 150 ft. by 3 ft. by 7 ft. deep all over would only hold 215,870 gallons, and if it slopes up to a shallow depth, as sketch denotes, necessarily much less still. However, I give the formula I would suggest for calculating the size of pipe, providing bottom of bath was horizontal, and at, or not much below, the invert of pipe:

$$D = \frac{1}{15} \sqrt{\frac{G^2 L}{H}}$$

where D = diameter of pipe in inches
G = number of gallons per hour
L = length of pipe in yards
H = head of water in feet (Hawksley.)

and in this case would be half the difference of level between invert of pipe and high-water line. By this working we should have an error on the safe side, partly owing to a small portion of contents of bath being below the pipe, and partly owing to the head being measured from invert instead of axis of pipe. This is allowing nothing for obstruction to the flow of water by the filter, and I take it that there would be some arrangement by which the mouth of pipe would be kept clear of gravel, and that the gravel would be coarse enough not to impede the requisite velocity of flow through it. From a few rough calculations I have made, I think the pipe would not have to be less than 18 in. diameter. I certainly think in a case of this kind—where the matter is complicated by the question of the filtering medium, and also by the sloping bottom of bath—that the best way is to make a small working model to scale, and experiment with a few sizes of pipes. The expense would be trifling, and the trouble really not much. I shall be pleased to add any further information in my power, and should like to see opinions of other readers of the “B.N.”—N. B. D.

[10870].—Dry Rot.—The whole of the timber must be carefully examined, and every particle affected by dry rot removed. If the spores have penetrated the brickwork the joints must be thoroughly raked out as deeply as possible, and repointed in Portland cement. Should the plaster of ceilings or walls show signs of being affected, this should also be removed. After clearing away all material affected by the fungi, thoroughly saturate the remaining and adjoining timbers and brickwork with the solution known as “weed killer,” made by the Horticultural Chemical Company, Milton street, Glasgow, diluting each quart of same with, say, a gallon of water. This is a very inexpensive chemical preparation, which I have found most effectual in arresting the ravages of this most insidious and insinuating enemy. I should also dress the new timbers with the same preparation, giving two or three coats. In replacing wall-plates or sleepers be careful to keep them free from the walls. In nine cases out of ten it will be found that the dry rot originates in the sleeper walls or ends of timbers carried into damp walls, or from wood blocks or plugs built in for fixing skirtings, &c. This can generally be avoided by trimming or corbelling. If “Ex-wise-ed” can spare the funds, I think he would find it advantageous to construct a dry area round the outside of the basement wall, or at least, to render the inside with Portland cement in lieu of plaster. I need hardly add that the new timbers and woodwork should be thoroughly dry, and, if not absolutely necessary, the underside of ground floor joists should not be ceiled, but left exposed to the air. I have found that the fungi will flourish and spread in both plaster and mortar, and have known the spores to travel through a brick wall 8 ft. in thickness, but to stop short at a thin facing of Portland cement. Everything depends upon the thoroughness with which the operations are carried out; but I have found that by following the method above advocated the fungi can be completely destroyed. Some two years ago I had occasion to deal with a floor the joists of which for a distance of about 5 ft. from the wall were thoroughly impregnated with dry rot. To avoid disturbing the whole of the floor, which would have caused serious inconvenience, I had the affected portions of the joists carefully adzed off where possible, and the remaining thickness saturated with the above-mentioned preparation, as well as the brickwork in which the disease appeared to originate, and on examining the floor recently no sign of any further decay appeared, and in many similar instances I have found it entirely successful. I must, however, add a word of caution—viz., that the “weed killer” is a strong poison, and should therefore be used with discretion, and the vessel containing it kept under lock and key.—E. CHART.

[10870].—Dry Rot.—Scraping off the fungi, and afterwards painting with red-lead, is not quite radical enough

to cure the ravages of dry rot. "Ex-wise-ed" will probably find the fungus behind the timber and in the joints of the brickwork. The writer had a case this summer where he found the fungus 4½ in. from the face of the wall. It is easy yet to say whether the rot is cured, but we dealt with it in the following way:—Removed all affected woodwork, cut away 4½ in. of brickwork from the face of the affected walls, dressed the place with coppers and quicklime (hot), set new bricks in cement, and fixed new woodwork. This is somewhat expensive; but a cure for dry-rot is cheap at any price.—DEPUTY B.E.

[10870].—**Dry Rot.**—The situation of the house is unfortunate, so near a bank, the drainage of which must always keep the cellars damp. Ventilation is necessary, and no doubt the want of an air current caused the disease in the first instance. The dressing of turps and red-lead on the new timbers was undesirable; the timber would, in fact, have been better without such paint, as it stopped the pores and confined the moisture inside. Painting, and even creosote, only kills the *mycelium* on the outer skin; but does not affect the interior of the wood. I should advise all the rotten timber to be removed, and well-dried timber substituted, the ends of all joists and timber being creosoted. The brickwork should be thoroughly dry or covered with asphalt; but every vestige of the diseased timber or spores should be removed or burned. I should cover the whole of the floor of cellar and walls with asphalt, or some impervious solution.—G. H. G.

[10871].—**Overhanging Cornices.**—An adjoining owner can complain if no prescription or easement has been acquired. If the cornice or eaves project so as to discharge rain-water upon the neighbour's property, it is a nuisance for which an action will lie. But an overhanging eaves cannot be interfered with if the right has been acquired by user. In any case I should advise "G. T." to avoid the projection by having an internal gutter, as it is clearly against the local bylaws; or otherwise to obtain consent of his neighbour.—G. H. C.

[10872].—**Covering Area of Building with Concrete.**—The rule is in operation, and ought to be enforced. The recent by-laws of the L.C.C. under section 16 of the Metropolitan Management and Building Acts Amendment Act 1878, make it compulsory to coat the "site of every house with a layer of good concrete at least 6 in. thick." If any house built since Oct. 1891, is without this layer it is certainly a violation of the by-law.—G. H. G.

[10873].—**Boasting.**—"Boasted" work in masonry means covering the entire face of the stonework with parallel lines, about ten to the inch, and producing a corduroy appearance. The boaster is a chisel 2½ in. or 2 in. wide. A good mason will make the lines vertical, whilst a careless or incompetent man will make an angle of ten or more degrees from the perpendicular.—ONE WHO DOESN'T MIND TELLING.

[10875].—**Drainage of Dwelling-Houses.**—Where it can be done, I both advise and practise the disconnection of the soil-pipe at or near its foot from the main drain of the house. I think this is especially advisable in mansion houses where there are a number of closets, and some of them at times not used for weeks or months.—W. P. BUCHAN.

[10876].—**Cistern.**—Some twelve months ago I had to deal with a lead-lined cistern that was eaten away in a similar manner to that described by "Tecton," though in this case there were no copper gutters near. I believe the corrosion arises from the particularly powerful effect which soft rain-water has in dissolving lead. The only cure is to remove the lead cistern and employ galvanised iron.—GILBERT W.

CHIPS.

At the last meeting of the Warwickshire County Council the asylums committee were authorised to employ an architect to prepare plans and estimates for the extension of the existing asylums.

On Friday last, the 28th ult., Colonel Luard, R.E., inspector Local Government Board, held an inquiry at Littlehampton with reference to an application of the local board for power to borrow £1,200, wherewith to erect offices. Mr. A. Shelley, clerk to the local authority, gave evidence as to the board's proposals, and the surveyor, Mr. H. Howard, F.S.I., produced and explained the plans.

Messrs. Baird, Thompson, and Co. have recently patented and are introducing an entirely new complete system of automatic and mechanical ventilation and warming, which can be readily adapted for the ventilation or warming (or conjointly as may be required) of all kinds of public and private buildings, schools, hospitals, sewers, mines, ships, &c., &c. A representative of the firm sailed by the Orient liner steamship *Ormuz*, on the 21st ult., en route for Australia, for the purpose of introducing their system into several important buildings. While there he will make an extended tour throughout Australia, besides visiting other parts abroad. Messrs. Baird, Thompson, and Co. have purchased the patent rights, models, and working plant, together with the goodwill of the business of Messrs. T. W. Greenwood and Co., ventilating and heating engineers, of Birmingham and Manchester, and it will be continued by them in all its departments, the whole of the present staff being retained, while Mr. T. W. Greenwood has been appointed district manager and representative. In order to cope with their increasing business, and to greatly further facilities for the expedition of contracts entrusted to them, plans are being prepared for new works, besides extensions to their present works; and a new department has been lately added—viz., that of sanitary drainage, water supply and analysis, and electric lighting.

Legal.

CONTRACTS FOR WORKS AND SERVICES.

UNDER the short title of "Labour Contracts" (Crosby Lockwood and Co.), Mr. T. F. Uttley, solicitor, has edited the fourth edition of the well-known handbook by David Gibbons upon the law of contract for works and services. In doing so he has brought the book down to date by quoting recent cases, and by adding a very useful appendix of what may be termed Labour Statutes from the Truck Acts, 1831 and 1887, to the Shop Hours Act, 1892, thus giving the full text of 14 important statutes, and including the Factory Acts, and Acts affecting master and workman, employers' liability, trade-unions, and arbitration. A few forms are added which may be useful in small matters. The book is carefully written as far as it goes; but the chapters are rather general, and it would have been more useful for reference if less notice had been taken of the older authorities and the new statutes had been more specially and separately considered. As it now stands the book gives one the impression of having been somewhat roughly thrown together and added to as occasion required, and it would be much better with most of the old cases struck out and the whole subject-matter rearranged in convenient sections. Still, there is a good deal of reading in the book that may well be useful to those concerned in the hiring of workmen.

But the law is so rapidly changing in its view of labour and labour contracts that it is not easy to see where we stand. The operations of trade-unions have done a great deal to make the task of carrying out building contracts a matter of much risk and difficulty. Yet this only the beginning of changes that are actually impending. As these come about, it will be necessary for those who draw up, and those who work under, such contracts, to provide for new risks and further liabilities. There is no doubt that we are about to witness some changes in the hours of labour, which must mean a rise in wages. It is quite certain that the unsettled question of employers' liability for accidents will not remain much longer in its present attitude of confused compromise. Probably masters will be made liable for all accidents, except such as clearly arise from the fault of the men themselves. If this is done, then the only way out of it will be for employers to cast the increased risk upon the insurance offices who do this class of business, and add their premiums to their trade expenses. In this way the charge will fall upon the customer by increasing the cost of production, and will have to be allowed for in any estimate and contract for works. Another coming change is probable to be found in the appointment of Court of Arbitration for the prevention and settlement of strikes, a change that would be beneficial to all concerned. The recognition of the claims of labour is no new thing, it is clearly written in our "Statute Book," but the progress made so far has given a great impetus to the movement, which is now going forward at a much more rapid rate. The true business aspect of the question is to recognise the coming changes, and to reckon for them as far as possible in all labour contracts. FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

PERPLEXED.—WALL.—WINDOWS.—You cannot prevent an adjoining owner from opening windows overlooking your premises. But you can erect a hoarding or wall, or anything else on your own ground, and so block them up and prevent them becoming ancient lights. Probably if a hoarding is put up, he will consent to close them, or some written agreement may be made, and rent paid, when no rights would accrue.

A Wesleyan chapel is about to be built adjoining an existing Sunday-school at Bishopston, near Bristol, at a cost of £3,000. Mr. Herbert Jones, of Bristol, is the architect.

Acting on instructions from the Baroness Burdett-Coutts, Mr. Richard Sisk, builder of the Baltimore Piscatorial Industrial School, is constructing a model of that institution for exhibition at the Chicago World's Fair. The work will occupy some months, and the completed model will be about the size of a cottage of medium dimensions.

LEGAL INTELLIGENCE.

THE EXTRAORDINARY CHARGE AGAINST A LOCAL BOARD SURVEYOR.—We regret that, by a printer's error in our report (p. 619 last week) of this absurd and unfounded charge against a surveyor to a local authority, "Southport" was substituted for "Stourport." Mr. William Crabtree, who has been the surveyor to the borough of Southport for the past quarter of a century, kindly draws our attention to this error, and we are indebted to him for his courtesy.

A BANKRUPT BUILDER REFUSED HIS DISCHARGE.—At the Swansea County Court, on Oct. 28th, application was made on behalf of David Richards, formerly a builder, trading as Richards and Son, of 5, Melbourne-place, and of Northampton Yard, Swansea, for his discharge in bankruptcy. The Official Receiver's report showed that the receiving order was made in 1884, and the liabilities were £1,491 1s. 3d., and the assets, after deducting preferential claims, £306 6s. 10d., and a dividend of 3s. 2½d. had been paid. The debtor omitted to keep usual and proper books of account, and as to sufficiently disclose his business transactions and financial position within the three years immediately preceding his bankruptcy. After examining the debtor, the judge expressed his surprise at the recklessness he had shown. The application was refused.

DEFECTS IN THE EMPLOYERS' LIABILITY ACT.

—His Honour Judge Ellison gave his decision, on Oct. 27, in the action brought in the Sheffield County Court by Thomas Silcock, a bricklayer, against Walter Shaw, builder, Abbeydale-road, to recover £15 under the Employers' Liability Act. The plaintiff sustained the injuries by the fall of a scaffolding on which he was working while in defendant's employ. The scaffold had been put up by Martin Connor, who, according to plaintiff's case, was foreman scaffolder. But the evidence called for the defendant showed that so far from being a foreman scaffolder, Connor was only an ordinary bricklayer, and was at the time engaged on another job when one of the men fetched him to put the scaffolding up. So that not only was he not intrusted with the work, but in doing it he was committing a breach of duty by neglecting his own job. The plaintiff's case, therefore, entirely failed, and it was another illustration of the way in which these cases did fail, because the defendant, being a builder in a very small way, had apparently no such thing as a foreman. Any scaffolding had to be erected by the men amongst themselves, and therefore, as no one was intrusted with the work at all, there could be no possibility of recovering under this Act of Parliament, because it would be a case of common employment. Judgment would be for the defendant, but he did not think there ought to be any costs.

PAYMENT FOR THE TOOL-GRINDING HOUR.

—Mr. Charles Wall, a builder, of Chelsea, was summoned at Highgate police-court on Monday to show cause why he should not pay the sum of 10d. The complainant said he was employed by the defendant as a bricklayer, and at the completion of the job was discharged, when he was paid in full, with the exception of 10d. (one hour's pay). The custom of the building trade was to pay bricklayers an hour's pay over and above the time they had put in. The plaintiff produced the rules of the society to prove this. The Society had found the money for him to go on with the case. The defendant did not appear, but had paid the money into court.

CURIOUS ACTION BY AN UNDISCHARGED BANKRUPT.

—At the Norwich County-court on Oct. 26, William Evans, Stanley-road, Northgate-street, Great Yarmouth, builder, sued his cousin, James Evans, Nelson-street, Norwich, builder, to recover the sum of £29 13s. 8d., balance due for tools detained and arrears of wages. Plaintiff said that on June 22nd, 1891, he was adjudicated bankrupt, and was still an undischarged bankrupt. Under the bankruptcy he was allowed certain tools, including hammers, cramps, saws, &c., and others to the value of £5. It was arranged that he should go as manager of defendant's business at South Walsham, at the wages of 30s. a week. He received £1 a week, a payment on account, it being understood when the books were made up that he should receive the back money. His connection with the South Walsham business closed in March last, when he received a notice of dismissal from the defendant, who alleged that he had received certain moneys on account of the firm without accounting for them, and forbade him to go upon the premises again. His Honour thought it had not been shown that there was any agreement to pay more than 20s. a week, and entered judgment for defendant with costs.

WHAT IS A WAREHOUSE UNDER THE BUILDING ACT?—At Bow-street, on Tuesday, Messrs. Holland and Hannen, builders, Duke-street, Bloomsbury, appeared in an adjourned summons charging them with infringing the fourth subsection of the 27th section of the Metropolitan Buildings Act. The case was heard a month since, when Mr. Vaughn

reserved his decision. (See report in the BUILDING NEWS for the 7th ult., p. 513.) In giving judgment, Mr. Vaughan said:—This summons has been taken out by Mr. Wallen, the district surveyor of St. Pancras, against Messrs. Holland and Hannen for irregularities in the construction of a building in Grafton-street, contiguous to the premises of Messrs. Shoobred, and intended, when completed, to form an extension of those premises, and for non-compliance with a notice requiring such irregularities to be amended. The building consists of eight stories, and its total height is 87ft. Mr. Ovenden, the architect, stated that the basement is to be used for packing goods, and the ground floor as a retail shop; that three floors immediately above are to be used as dining-rooms, and that the floors above them are to be used—one as a scullery and the other as a kitchen. A staircase leads from Grafton-street to the top of the buildings. There are four openings intended for lifts running through. The cubical contents of the whole building are 272,800ft., exclusive of the staircase, which is 16,656c.ft. additional. The cubical contents of the rooms above the concrete floor are 62,087ft. Mr. Wallen complains that the provisions of the fourth subsection of the 27th section of the Metropolitan Buildings Act have not been observed. By this subsection it is enacted, "That every warehouse or other building, used either wholly or in part for the purposes of trade or manufacture, containing more than 216,000c.ft., shall be divided by party-walls in such manner that the contents of each division shall not exceed the above-mentioned number of cubic feet. The first question that arises, then, is this:—Is this a building to be used either wholly or in part for the purpose of trade? That question must be answered in the affirmative. The next question that arises is the definition of a dwelling-house. Is this a building so constructed as to contain more than 216,000c.ft., and, if it does, is it so divided by party-walls as that each division shall not contain more than that number of cubic feet? In no sense can it be said that the statutory provision has been complied with. The complaint in this summons is well founded, and I am therefore compelled to make an order that the irregularities complained of shall be amended. Mr. Vaughan decided to allow £6 6s. costs, and agreed to state a case.

A MODEL WINDMILL AFFIRMED TO BE A SKY SIGN.—In the Queen's Bench Division on Tuesday, before Justices Mathew and Bruce, the appeal case of the "London County Council v. Carwardine and Co."—an appeal from a decision of Mr. Rose, sitting at Worship-street—was heard. The case was reported in our issues of March 18 (p. 423, last vol.) and July 15 of this year (p. 94, ante), when the case came before Justices Wright and Collins, and was referred back to the magistrate for restatement. The respondents were flour dealers in the City-road, and had upon the top of their premises a tower, on which there was a large model windmill, upon which there was a trade announcement. In addition to this, however, the mill was used for doing useful work, such as grinding flour, it lifted and lowered sacks of grain, and it worked a dynamo for the production of electricity. The County Council summoned the respondents before the magistrate upon the ground that the mill, with the inscription that it carried, was a "sky sign" within the meaning of section 2 of the Sky Signs Act of 1891. This statute defined sky sign as being any word, letter, model, sign, device, or representation in the nature of advertisement, announcement, or direction, over any building or structure, or upon any pole, standard, or other support. The magistrate held that this structure, with the letters upon it, did not constitute a sky sign within the meaning of the statute, but, at the instance of the County Council, he stated a case for the opinion of their Lordships. Mr. Justice Mathew expressed his opinion that what was complained of here by the County Council was a sky sign within the meaning of the Statute, and therefore that the appeal must be allowed. Mr. Justice Bruce concurred, and the case was ordered to be remitted to the magistrate, with an expression of the opinion of their Lordships.

THE LIVERPOOL JEWELLER AND HIS ARCHITECT.—At the Liverpool County Court, on Monday, before Judge Shand, John Byrne, jeweller, of Bold-street, sued Henry May, architect, 24, North John-street, for £48 6s. 6d., balance of money lent and amount of jewelry supplied. The defendant put in a counter-claim for £56 17s. 6d. for professional services, consisting of the preparation of plans and estimates for alterations to premises in the occupation of the plaintiff. The judge gave judgment for plaintiff for the amount claimed, less three guineas allowed to the defendant on the counter-claim.

CONVERTING A COACH-HOUSE INTO A STABLE.—At Bow-street Police-court, on Tuesday, a summons against Messrs. Titmas and Sons, builders, Grafton-street, was heard. Mr. Wallen, district surveyor, stated that, contrary to the Act, defendants had inclosed with a wooden hoarding a coach-house which Messrs. Shoobred had converted into a stable. He contended that, if the stable were

inclosed at all, it should be by means of a brick wall. Mr. Vaughan, whilst agreeing with the district surveyor's interpretation of the Act, adjourned the case with a view to a settlement being arrived at.

TRAVELLING TIME AND FEES FOR WORKMEN.—At Marylebone Police-court, on Monday, Messrs. Allen and Sons, builders and contractors, of Palmerston Works, Kilburn, were summoned by eleven of their workmen for refusing to pay their return fare to Dunstable, also for the time occupied in the journey, contrary to a contract made in the first instance. The claims of the men amounted to over 7s. each, the total being £3 13s. 6d. John Clinch, a painter, said he and others were engaged by one of the defendant's foremen to go from London to Dunstable to perform work for the defendants. The arrangement was that they were to be paid the railway fare, lodging money, and for the time occupied in the journey. The defence was that, according to trade customs, the men were only engaged from the arrival on the job; but the magistrate decided in their favour.

DAMAGES FOR FALSE IMPRISONMENT.—In the Edmonton County-court last week, before Judge Abdy and a jury, the action of Saps v. Hewitt, commenced a fortnight previously, was concluded. Saps, a contractor for carting, of Tudor-grove, Hackney, sued the defendant, a builder, of Houndsfield House, Lower Edmonton, for £1 15s. 6d., balance of account, and £20 for false imprisonment. There was a counter-claim of £10, the value of some stone alleged to have been stolen. The plaintiff's case was that he and a man named Saville contracted to cart rubbish from some premises in the City-road. They carted, according to the reckoning of the carters, 18 loads; but the defendant disputed this, and said it was only 16. Plaintiff gave way on the point, and received from defendant's foreman £1 on account of the bill of £2 15s. 6d., leaving the balance sued for due. In the course of the carting it seems that the cartmen were asked to cart away some stone, and one of them did so in a cart belonging to defendant, but without his knowledge, and then disappeared. Some days later defendant, exasperated at not being able to trace the man, gave his late employer (the plaintiff) into custody; but did not appear in support of the charge. A verdict was given for plaintiff for the amount claimed, with costs.

IN RE A. HOOD.—Alfred Hood, builder and contractor, Bethnal Green, has furnished accounts showing liabilities £1,531, with assets £314. He commenced business in 1880, with about £250 capital. He attributes his failure to bad and doubtful debts, to losses on contracts, to loss in connection with a building speculation, and to law costs. The Official Receiver states that £306 of the assets are the subject of dispute, and of uncertain value. The debtor has been adjudged bankrupt.

ACTION BY MORTGAGEE AGAINST SURVEYOR.—DENNES v. GOULD.—This action, heard by Mr. Justice Wills on Saturday, raised the point whether the mortgagee of house property mortgaged by the building owner as security for advances to the builder can sue the surveyor who has been employed by the owner, the mortgagor, to act as valuer to certify for such advances for negligence in certifying for advances not really due in respect of work not duly executed. As reported in our issue of Aug. 19 last, p. 269, one Hunt was the owner in freehold of land at Ilfracombe on which he desired to erect houses, and proposed to mortgage to one Dennes (the plaintiff), who was to make the advances according to a schedule of advances. Hunt accordingly executed a mortgage to Dennes, the deed being attested by W. H. Gould, the surveyor to the local board of Ilfracombe, and whom Hunt employed to value the work as it was done and certify for instalments to be paid by Dennes. Hunt had entered into a contract with a builder to erect the houses, and from time to time Gould gave certificates, on which Dennes, the mortgagee, made advances, and on certificate of completion the final instalments were paid. Then it was found that the work had not been properly executed, and that, in particular, the drains had not been executed as they ought to have been; and Dennes then brought an action against Gould for negligently giving certificates for work not duly executed. The action was referred to Mr. Ridley, the Official Referee, who found that Gould had been guilty of gross negligence, though not of fraud, and that the damage done to Dennes amounted to £300; but he came to the conclusion, on the evidence, that there was no contract between Gould and Dennes, and that, according to the authorities, the action could not lie apart from contract. The plaintiff relied on a decision of Mr. Justice Chitty in "Carus v. Wilson," in which, however, a contract was set up, and the defendant relied on "Schoales v. Brook," a later decision of Mr. Justice Romer, confirmed by the Court of Appeal, that the action could not be maintained by the mortgagee unless there was a contract between him and the surveyor who acted as valuer to give the certificates, and so the Official Referee gave judgment for the defendant. The plaintiff appealed. The Court, without calling on

defendant's counsel, held that the Official Referee was right, and that the action could not be maintained.

A TEMPORARY BUILDING.—Mr. R. Eddie was summoned by the London County Council on Tuesday last for erecting a temporary building at the rear of a house in Tyndale-place, Islington. Mr. Chilvers appeared on behalf of the council, and called Mr. Henry Lovegrove, district surveyor, to give evidence of the construction and position of the structure, which was of wood covered with sheets of corrugated iron. The magistrate, Mr. Horace Smith, ordered a fine of £3 and £2 4s. costs.

ARCHITECTS' CHARGES.—In the Queen's Bench on Tuesday last, before Justice Vaughan Williams, the cause Williams and Hopton J. Hutton was tried. The plaintiffs were architects in practice in Regent-street (but have since dissolved), and were instructed to prepare drawings of houses and shops at Swanley. They also claimed for an amount paid to Messrs. Mills and Jones for bills of quantities. Mr. H. Lovegrove and Mr. Dudley gave evidence on professional custom, and stated that the charges were fair and reasonable, and in accordance with the practice for similar work. The jury gave a verdict for the plaintiffs for the amount claimed.

CHIPS.

A railway-station in Elysium-lane, Bensham, near Gateshead, was opened on Tuesday. The designs were prepared by Mr. William Bell, the North-Eastern Railway Company's architect, and Messrs. George Lister and Son, of Crook, were the contractors.

The London County Council decided on Tuesday that the height of hoardings upon which posters are displayed shall not, after a certain time, exceed 12ft. They instructed the Fire Brigade Committee not to wait until the council is prepared to employ its own labour, but to obtain tenders at once for the erection of a new fire-engine station in Queen's-road, New Cross, for which working drawings have been completed. The amended tender of the Thames Ironworks and Shipbuilding Company was accepted at \$54,353 for the reconstruction of Barking-road bridge.

The purchase of the common at West Wickham, near Hayes, Kent, by a body of subscribers, has now been effected, and the Lord Mayor elect, Alderman Knill, will visit the common and declare it open to the public on Saturday in next week, the 12th inst. The lord of the manor, Sir J. F. Lennard, required £2,000 for his rights, towards which the City Corporation contributed £500.

Mr. James Mansergh, C.E., has reported to the newly-formed town council of Southend-on-Sea upon the sewerage system. He recommends that the sewers be extended and improved at an estimated cost of £10,000, and that two new sewer outfalls of 30in. and 27in. diameter respectively be carried about one mile from the shore, the present outfalls for which they are substituted being utilised as storm overflows. The outlay on this portion of the scheme is estimated at a further £25,000.

The Mayor of Northampton received on Friday a letter from Lord Wantage, offering to the town of Northampton, as a People's Park, a large residence, known as Abington Abbey, and about twenty acres of wooded ground, within two miles of the centre of the town. In recent years the Abbey has been used as a private lunatic asylum. On the lawn is a mulberry tree planted by Garrick in 1778.

The prizes awarded to competitors in the recent exhibition promoted by the Turners' Company were distributed by the Lord Mayor at the Mansion House on Friday. The chief of these was the Freedom of the Company and of the City of London, together with a silver medal and five guineas, awarded to Mr. J. Lawington, of Duck-lane, Soho, W.

The Bishop of Rochester dedicated on Saturday the first portion of the permanent building of the Gonville and Caius College Mission and Settlement, which has been erected at the corner of Holman and Harroway-roads, Battersea. The building will cost £6,000. It will consist of a large hall seating about 500 persons, and an annexe providing kitchen, caretaker's rooms, and club, in addition to classrooms. The upper floor of the main building is to be devoted entirely to church work.

The opening of the new schools in connection with St. Wilfred's Roman Catholic Church at Northwich took place last week. The structure is built in brick, with mullions of moulded bricks. The school is capable of seating 150 children. Mr. J. Cawley, of Northwich, is the architect, and Messrs. Clarke and Sons, of Middlewich, the contractors.

The managers of the Poplar and Stepney Sick Asylum have decided to enlarge their premises in Devons-road, E. The tender of Mr. J. Holland, of Poplar, amounting to £23,591, has been accepted for the work.

WATER SUPPLY AND SANITARY MATTERS.

SEWAGE PRECIPITATION WORKS AT WOODVILLE.
—For a long time past a stream flowing through Lord Carnarvon's property, near Burton-on-Trent, has been polluted by crude sewage discharged from the various factories situated at Woodville. A few months ago the directors of Messrs. Brunt, Bucknall, and Co.'s brewery, which produces a large volume of sewage and waste liquor, determined to set an example to their neighbours by erecting works for chemically treating the sewage. The works have been designed by Mr. Albert Wollheim, Assoc. M. Inst. C.E., of Leadenhall House, London, E.C. The sewage can be treated either during the entire day or accumulated in a siphon tank and treated only during the several discharges of the latter, and an electrical alarm will be connected with the office to give timely warning of each discharge. A night storage tank has also been provided. The precipitation tanks are in duplicate, and can be worked either on the continuous or separate systems. The treatment will be by the "Amines" process, which has been adopted on account of its property of destroying all germs capable of producing putrefaction, fermentation, or secondary decomposition.

TODMORDEN.—Mr. F. H. Tulloch, A.M.I.C.E., Local Government Board Inspector, held a public inquiry at the Town Hall, Todmorden, on Thursday, the 27th ult., in regard to the application of the Local Board for borrowing powers for loans of £5,600. Of this sum it is proposed to devote £1,600 for the decorations of the interior of the Town Hall, and £4,000 for sewerage of the Walsden district. The inspector afterwards visited the proposed line of sewer, accompanied by Mr. Shaw, A.M.I.C.E., surveyor, and Mr. Blackburn, nuisance inspector. The Local Board members have decided to sign the necessary documents for the purchase of the three gasworks in the Todmorden district, and to promote a Bill in Parliament for that purpose. The total amount of purchase money is £103,362 10s., equal to about 18½ years' purchase on the average profits.

CHIPS.

The laying of the foundation-stone of a new brewery in the High-road, Tottenham, which is being erected partly on the site of an old one established in 1824, took place last week. The architect is Mr. Wm. Bradford, and the builders are Messrs. Reed, Blight, and Co., of Plymouth.

The Linlithgowshire County Council have adopted a report by Messrs. Leslie and Reid, civil engineers, Edinburgh, for providing a water supply for the village of Linlithgow Bridge.

A north aisle, just added to All Saints' Church, Botley, Hants, was dedicated on Tuesday week. The church is Early English in style, and was built in 1836. The new aisle has been built from designs by Mr. T. Graham Jackson, A.R.A. The walls are of Swanage stone, with Doulton stone dressings, and the inside supported on open columns. The accommodation has been increased from 225 to 300 sittings. Mr. J. C. Bailey was the contractor.

The adjourned case of Joseph George Rogers, builder, of Timpon-road, Landport, and a member of the Portsmouth Town Council, came before the local Bankruptcy court last week, and was further adjourned till Nov. 14th, to allow of the preparation of accounts. The case is one of those arising out of the Portsea Island Building Society failure.

The parish church of Llanabhaiarn was reopened on Friday after restoration, from the designs of Mr. Kennedy, the work being carried out by Mr. Evan Williams, Bangor. The Bishop of Bangor preached.

The inaugural address of the new practical school for decorators in connection with Heriot-Watt College, Edinburgh, was delivered on Tuesday night by Mr. D. J. Vallance, lecturer on Ornament and Decoration in the College. The lecturer explained that the classes would be of an entirely practical character, but that for that evening he would treat the subject of the decorator's art from a more general point of view.

At the last meeting of the municipal buildings committee for Bth City, Mr. J. M. Brydon, F.R.I.B.A., presented the amended plans, which provide for the shortening of each wing of the building, throwing the space thus acquired into the roadway. The new plans were recommended to the council for adoption.

The foundation-stone of the new chancel and transepts of Weston parish church, near Bath, has just been laid by Mrs. Fraser, widow of the late Bishop of Manchester. The work is being carried out by Messrs. Stephens and Bastow, contractors, of Bristol, from the plans of Mr. E. H. Harbottle, architect, of Exeter. It will cost about £4,000, including the new oak seating in the existing nave.

Our Office Table.

MESSRS. ASTON WEBB AND INGRESS BELL have been appointed the architects for the new buildings about to be erected in Whitehall for the United Service Institution. Inigo Jones's banqueting hall, long used as a Chapel Royal, will be incorporated as the hall of the Institute, and the new buildings are to occupy the site adjoining, where the stables and mews are now in course of demolition. This work will greatly add to the architectural importance of one of the most important thoroughfares in London.

At last week's meeting of the London School Board, the Works Committee again presented a report recommending that competitive plans be invited for one of the new schools about to be built. In the report they stated that they considered the tenders accepted by the Board for schools lately planned very costly. They therefore recommended that they be instructed to prepare and submit to the board the conditions for a competition for the school proposed to be built in Priory-street, Bromley. General Moberley moved the adoption of this report, but discussion on the matter was postponed.

The architects of the Province of Quebec are complaining of the action of the Provincial Government in imposing upon them a professional tax, thus placing them on the same footing as lawyers and doctors, while at the same time refusing to their association the rights and privileges accorded to the other professions. They object, and with great reason, to being recognised as a profession for taxation purposes only.

In an interesting communication to *A.A. Notes* for November, Mr. Fred W. Marks, now in London, describes the progress that is being made by the Australian colonies. As to the prospects of architects, he says:—"Australia requires no more architects at present. There are upwards of 600 already practising there, while 100 or more are employed in Government offices; counting assistants and pupils, it is estimated that 2,000 persons are engaged in architectural work in these colonies (to say nothing of jerry builders)." The rates of wages are high, the average being: bricklayers, 11s. to 12s. per day; carpenters and joiners, 10s.; labourers, 7s. to 9s.; plasterers, 7s. to 11s.; plumbers, 10s. to 11s.; quarrymen, 10s. to 10s.; slaters and stonemasons each 10s. to 12s. daily.

A NEW method of brick manufacture, used in certain parts of Central Asia, was recently described to the Paris Academy of Sciences by M. Edouard Blanc. This mode of manufacture is practised by the tribes in Western Mongolia, on the frontier of Siberia. The extremes of temperature render a brick of great durability a necessity of life. This is attained by the use of steam. The oven is cylindrical, and surmounted by a hemispherical cap, which is kept open for the first three days. The bricks, about 7,000 at a time, are baked by means of a fire fed by about 7,000 kilos. of an annual ligneous plant, the *Alhagi camelorum*. On the third day the opening is closed with felt, which is kept constantly wetted, so that the bricks are inclosed in a steam bath, while kept at red heat. The bricks, red after the first period, appear dark grey after the second part of the process. Their structure is porous; they become sonorous, and acquire a great hardness. They show a striking resemblance to certain trachytes. Made from the same clay as our bricks, they are said to resist weathering very much better.

THE *Neue Freie Presse* of Vienna discusses the advantages and disadvantages which attend the electric lighting of St. Stephen's Cathedral, which has lately been introduced. From a practical point of view the lighting is all that could be hoped for. The twelve large hanging lamps, each 1,000 candle-light power, suffice to spread a brilliant light into every part of the great church. The light also brings out the details of decoration and of the architecture as it is never possible to see it under other conditions, because no other light is so equally distributed from the ceiling to the ground. But this may not be altogether an advantage, as an architect naturally arranges his parts with distinct reference to the distribution of light, as it is permitted to enter by the windows or dome. And as regards the building as a whole, its appearance is certainly not improved by the absence of due shade. What is here stated must

apply more or less to all large Gothic buildings. The fault lies not in the strength of the light, but in its position. It can never have the same effect as that got by the sun's rays entering through side windows, and it was with reference to such lights that Gothic cathedrals were built.

ACCORDING to the returns published by the French Minister of Public Works, the total length of navigable rivers and canals in France last year was 7,995 miles, of which 2,735 miles were rivers navigable by nature, 2,250 miles rivers which had been rendered navigable by dredging, and the rest canals. The total quantity of goods carried upon these waterways was 25,181,056 tons, or 1,013,713 tons more than in 1890, the increase in the traffic being much greater on the canals than on the rivers. More than 50 per cent. of the imports (2,125,407 tons) consist of combustibles brought from the coal-fields of Mons and Charleroi, while the exports (887,230 tons) are almost entirely composed of goods sent to Belgium.

An examination of candidates for certificates of registration from the Plumbers' Company was held on Saturday at the new Borough-road Polytechnic Institute. The examiners were Messrs. Charles Hudson (chairman), W. H. Webb and J. Knight (master plumbers), H. Hobbs (Battersea Lodge), G. E. Munn (East London Lodge), and R. A. Nurse (No. 1 Lodge), of the United Operative Plumbers' Association of Great Britain and Ireland; and Mr. C. T. Millis, M.I.M.E., principal of the educational department of the institute. In addition to undergoing a practical test, each candidate was required to answer a series of questions relating to the various materials used by plumbers and the general sanitary arrangements of a dwelling house. Of the 24 candidates who presented themselves, only three succeeded in passing the full examination. 54 students have joined the plumbing classes held at the institute since the opening of the classes on the 3rd inst.

A TRAMWAY recently established at Berne is worked on the compressed-air system, owing to the gradient being too stiff for horses to haul the cars. The cars are self-contained, and are on the Mekarski system, the compressed air being contained on the cars in reservoirs. Each car carries twelve reservoirs, ten of which are arranged on the underframe and two under the seats. These vessels, which contain air under a pressure of 600lb., are connected with one another and with the motor. The rails, which are of steel, are so profiled that they also form longitudinal sleepers, and the gauge of the line is 40in. A ten minutes' service of cars is made, and the speed ranges from 7½ to 9½ miles an hour.

MEETINGS FOR THE ENSUING WEEK

MONDAY.—Royal Institute of British Architects. Opening Address of the President, J. Macvicar Anderson. 8 p.m.

Society of Engineers. "The Use of Steel Needles in Driving a Tunnel at King's Cross," by W. H. Hottum. 7.30 p.m.

Liverpool Architectural Society. "Questions of the Hour," by T. Mel-lard Reade. 6.30 p.m.

TUESDAY.—Institution of Civil Engineers. Opening Meeting of Session. 8 p.m.

The Euclid-avenue Opera House, at Cleveland, Ohio, the finest theatre in that city, was destroyed by fire on Saturday. Scenery, costumes, and apparatus valued at £5,000 have been lost. The house itself was insured for £50,000.

The City Corporation Art Gallery was formally reopened last week on the completion of alterations, including the improvement of the lighting. Many of the pictures have been rearranged, and some of the more costly have been glazed. The valuable gift of the late ex-Sheriff Nissen, comprising 54 drawings of Old London Bridge, by E. W. Cooke, R.A., have been hung in the smaller gallery, and are now to be seen to greater advantage than was the case formerly.

The Vicar of Camberwell appeals for funds to complete the restoration of Sir Gilbert Scott's early success, St. Giles's parish church; the tower and spire of which were pronounced unsafe a year ago, owing to the perishable nature of the Caen stone used in construction. The restoration is being carried out, under the direction of Messrs. Newman and Newman, by Messrs. B. Colls and Sons, of Coleman-street, E.C., in three sections. Of these the first and second, for the spire were taken at £1,100 and £1,250 respectively, and are almost completed; while No. 3, for the tower, will cost £1,150.

Trade News.

WAGES MOVEMENTS.

DUNDEE.—The recent dispute between the plumbers' apprentices in attendance at the Dundee Technical Institute plumbing classes and the Technical Institute Committee has reached an acute stage. The plumbers protested against the apprentice tinsmiths being allowed to attend practical plumbing classes, it being considered that they were not entitled to avail themselves of the classes having regard to their want of training in workshops. On Friday night the class met as usual, when a communication was read from the Institute Committee, declining to restrict the classes. The plumbers afterwards met and decided to break off their connection from both theoretical and practical classes.

SALFORD.—At their October council meeting, the council passed a resolution on the motion of Councillor Huddart (labour) to the effect that "every corporation contract for the supply of any goods, or for work done, shall contain an undertaking on behalf of the contractor that all workpeople employed in connection with such contract shall be paid the standard rate of wages current in the district where the work is carried out; and in case of any violation of this undertaking, the contract shall be null and void, and the contractor liable for any loss caused thereby."

WORKING RULES FOR THE BUILDING TRADES OF LONDON.—The new code of working rules for the Metropolitan, agreed to in June last at the conference of the master builders and the representatives of all the trades concerned, comes into force on Monday next, the 7th inst., although by special arrangement the bricklayers have enjoyed the increased rate of pay since July. The plumbers will have a different set of rules to the other trades. The chief points are that for all trades, except plumbers, the working hours are 50 per week in the 38 weeks of summer, 44½ hours for eight weeks in the depth of winter, and 47 hours for the intervening three weeks between seasons in November and February. The rate of wages is advanced by ½d. an hour all round, and overtime is reckoned at time and a quarter till 8 p.m., time and a half from 8 till 10 p.m. and after that hour; and after 4 p.m. on Saturdays, and throughout Sunday at double time. For these trades the London district extends to a twelve-mile radius from Charing Cross. For plumbers the working hours are 47 hours in summer, 42 in mid-winter, 44½ hours in the first and last three weeks. The late rate of wages is advanced by ½d. per hour, but the "London district" in which the rules are in force is restricted to six miles from Charing Cross, and payment for overtime remains as before.

Two handsome stained-glass windows in memory of the late Archdeacon Balston, vicar of Bakewell, and formerly head master of Eton, which have been placed in the chancel of Bakewell Church, were dedicated on Friday afternoon by the Bishop of Southwell. The design represents the *Te Deum*, and the window has been erected at a cost of £600.

The building committee of the Olivet Chapel, Stanningley, near Leeds, have selected the plan of Mr. Hancock, Batley, for a new chapel. The plan provides for accommodation for 500 persons, and separate school buildings with equal accommodation. In the school there will be 16 classrooms, with gallery overhead. The premises will be substantially built of stone, and a tower will be placed over the entrance. The cost will be £3,000.

CHIPS.

The local board of Gorton, near Manchester, have adopted plans and estimates prepared by Mr. C. J. Lomax, the engineer for the sewerage of the district, at an estimated cost of £28,534.

Public baths are about to be erected at Castleford, Yorks, from plans by Mr. A. Hartley, architect.

A new hotel is in course of erection at Shooter's Hill West Cotes, at a cost of over £2,000. The architect is Mr. Tompkins, of Cotes.

A large party of Edinburgh builders and their friends visited Edinburgh Castle on Saturday afternoon, and were conducted over the historic buildings by Mr. Hippolyte J. Blanc, A.R.S.A., the architect of the restorations. In particular he traced the history of Parliament Hall and the Argyle Tower, pointed out the features of the restoration of these buildings, and the considerations which had guided him in the style of restoration adopted.

Alderman Simpson will be elected Mayor of Harrogate on Wednesday next. He is a native of the city, was born in the year 1824, and was apprenticed to the building trade, which he followed with success until his retirement a few years ago. In the year 1870 he was elected a member of the improvement commissioners, and since that time he has never ceased to serve the town in a public capacity. Perhaps his best work was the discovery of two valuable mineral springs in Low Harrogate, the yield of one of which is only second to the old sulphur spring.

Mr. F. H. Tulloch, A.M.I.C.E., a Local Government Board Inspector, held a public inquiry at Todmorden on Friday relative to the local board's application for sanction to borrow £4,000 for Walsden sewerage, £1,600 for improvements to the town hall, £1,000 for painting and decorating, and £600 for heating and ventilation. No opposition was offered.

The will of Mr. Ralph Ratcliff, late of Providence Villa, Harlington, Middlesex, brick manufacturer, who died on August 23, has been proved, the value of the personal estate amounting to upwards of £19,000.

At the last meeting of the town council of Manchester the mayor announced that he had received an intimation that a number of gentlemen intended to present to the corporation a portrait of John Bright, painted by Knight in 1847.

A new fire station is under course of erection by the London County Council on a site in Lordship-lane contiguous to the new park at Dulwich, and the memorial stone was laid on Monday. The design is by Mr. Thomas Blashill, superintending architect to the Council. Messrs. Stimson and Co., of Brompton, are the builders, their contract having been taken at £10,610. Accommodation will be provided for an engineer, nine married firemen, and a married coachman, with a steamer, a manual engine, a hose-cart, four escapes, and two horses.

Holloway's Pills improve the appetite, strengthen the digestion, regulate the liver, and act as gentle aperients. These Pills are suited to all ages, and their inventor's fame has resounded through all quarters of the globe. Wherever sickness exists, this medicine has made its way to be everywhere and justly appreciated.

BILLS OF QUANTITIES & PLANS.

T. PETTITT and CO. Lithograph Bills of Quantities with the greatest expedition. Accurately copied from the draft in clear hand. Orders from the country returned by evening mail on the same day. Terms on application. Also Plans of Building Estates and General Plan Work at very reduced prices.—**T. PETTITT and CO.**, Lithographers, 28, Fenchurch-street, Soho, London, W. Established 50 years.

CRAIGLEITH STONE.

UNEQUALLED for Staircases, Steps, and Landings, especially for Public Buildings with great wear. **VERY HARD, and NEVER WEARS SLIPPERY.**

SOLE AGENTS for England, **J. & A. CREW**, Cumberland Market, London, N.W.

DOULTING FREESTONE.

THE CHELYNCH STONE.—The Stone from these Quarries is known as the "Weather Beds," and is of a very crystalline nature, and undoubtedly one of the most durable Stones in England.

THE BRAMBLEDITCH STONE is of the same crystalline nature as the Chelynych Stone, but finer in texture and more suitable for fine moulded work.

Prices, and every information given, on application to **CHARLES TRASK and SONS**, Doulting, Shepton Mallet, Somerset. London Agent:—**Mr. E. A. WILLIAMS**, 16, Craven-street, Strand, W.

HAM HILL STONE.

The attention of Architects is specially invited to the Durability and beautiful Colour of this material. Quarries Well Opened; Quick Despatch Guaranteed; Stonework Delivered and Fixed Complete. Samples and Estimates Free.

Address:—**THE HAM HILL STONE COMPANY**, NORTON, STOKE-UNDER-HAM, SOMERSET. London Agent:—**Mr. E. A. WILLIAMS**, 16, Craven-street, Strand W.C.

WM. OLIVER & SONS, MAHOGANY, WAINSCOT, WALNUT, TEAK, VENEER, and FANCYWOOD MERCHANTS,

120, BUNHILL ROW, LONDON, E.C. The most extensive Stock of every kind of Wood in Planks and Boards, dry and fit for immediate use.

TENDERS.

* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender: it adds to the value of the information.

COWES, I.W.—For the repair of the sea-wall for the East Cowes Local Board:—
Thomas (accepted) £43 15 0

GLASGOW.—For Glasgow sewerage:—
Contract No. 1:—
Johnson, S., Manchester £7,769 0 9
Hopkinson, R., Halifax 6,377 12 1
Kellett, E., Bradford 6,041 8 8
Brayshaw and Horrocks, Burnley 5,800 11 8
Atkinson, T. E., Cross Hills 5,565 0 6
Parkinson and Bower, Halifax 5,208 17 4
Taylor, G., Blackburn 5,180 12 7

FRIDAY, NOVEMBER 11, 1892.

ARCHITECTURAL "SURVIVALS."

A "SURVIVAL," in the language of modern science, is something which once had a use, and which Nature still continues to produce, although its use has ceased. Survivals are common amongst both animals and plants. Both of them, in numerous cases, retain features which, from a utilitarian point of view, are out of date. The time was when these features, of whatever sort, were invaluable to their possessors. But the conditions of life have changed; they are serviceable no longer, and yet, in spite of this, they show themselves still in generation after generation. Survivalism is common in nature; but it is still commoner in art, and of all arts, it is most common in our own. Theorists have written against it; enthusiasts have tried to dispense with it; but the fact remains that architecture, especially in Europe, has always been made up very largely of survivals.

It is well for the architect to have a lofty ideal of perfection. "Who aims at the sun shoots higher far than he who means a tree." We shall not quarrel, therefore, with the writers who assert that a building ought to derive all its beauty from the skilful treatment of its essential parts, and that, with the exception of sculpture and pure decoration, it should admit no details except those which spring inevitably from its purpose and its construction. Such a building, if beautiful, would certainly be above criticism. The difficulty is, that to produce it almost exceeds human powers. An architecture with no survivalism in it is a thing which Western artists, from the Greeks downwards, have never attained, and which, if we ever get knowledge enough to speak positively, we may perhaps find to have been equally beyond the reach of builders in the East. On a superficial view, however, it does seem as if the earlier Mohammedan architects—for instance, in Cairo—had come nearer to the theorists' ideal than either we or our forefathers. In the main, though not altogether, their apparent construction is also the real one; their ornament usually, though not always, is purely decorative. It may be a far-off suggestion of natural forms, it may be an original invention of beautiful patterns; but, with two or three obvious exceptions, it is not an imitation of human work. In this, to a large extent, lies the difference between the Eastern and Western Pointed styles—the Saracenic art and Gothic art. *A priori*, the former would seem most in the right, and yet how shallow, how frivolous, how superficial, is it compared with the latter!

We are most of us so busy in trying to produce art of some kind, and, if we are wise, we are seeking to produce it so much more by imagination and perception than by processes of reasoning, that few of us, perhaps, realise how much survivalism there is in our favourite styles. We need scarcely refer to the Greek Orders, with the numerous points which show their descent from wooden types of construction. The survivalism there has struck everybody. In Roman architecture it is even more conspicuous, though in a different way. The architrave and its frieze, the great stone beams or lintels which run from column to column, and supported the roof or the pediment, were, of course, the very essence of the construction in a Greek temple. It was these that really did the work and carried the weight, and it was not wonderful that they became a prominent feature. But when the Romans took up and

somewhat modified the three orders, they adopted, in many cases, the arch along with them. It was then the arch and not the lintel which became the important thing for practical purposes. The architrave and frieze were wanted no longer. Yet they survived. They were retained, though useless. The arch, which really kept the building up, was made, in appearance, a trivial and secondary matter, while the effete entablature lasted on in all its glory, and took the credit of the whole proceeding. It is the way of the world. They manage it so in "church, army, physic, law," as well as in architecture.

In the Post-Roman styles, the Romanesque and Lancet Gothic, this particular piece of survivalism went out of fashion. For a time, indeed, it was thought necessary to put a fraction of entablature above the capital of each column, even after the arch had asserted its own importance, and stepped into its rightful place. Modern copies of these curious bits of entablature may be seen inside some of Wren's churches, and in that of St. Martin's-in-the-Fields. Ancient modifications of them remain in the double capitals at St. Vital, Ravenna, and in other Byzantine churches. By degrees, however, the arched styles shook themselves free, not of survivalism itself, but simply of discordant survivals from earlier times. The architrave was abandoned, the frieze and the cornice grew smaller and smaller. Now, however, came in survivals of a different variety—a variety not unknown in Classic times, but unlike that which has been above referred to. Hitherto we have been speaking of the retention of structural features whose practical purpose has passed away. Now we come, in addition, to the imitation of structural features where they do not really exist. In strictness, this can hardly be called survivalism, and yet it is so closely allied to it, and so inseparably mixed up with it, that the two things cannot easily be separated. For want of a better name, it might be called *quasi-structuralism*. It is that copying of human work which Mr. Ruskin was once wont to anathematise as the sure mark of a decadent period. Every period, however—the best as well as the worst—is full of it. In Romanesque and Early Gothic the *quasi-structuralism* lies mainly in imitations of arches and columns. The walls are covered with arcades, whose arches rest on capitals, and these, apparently, on shafts. Really, they do no such thing. Whatever weight is above the arcade is carried either by the bonding of the arch-stones into the wall—so that they act, not as *voussoirs*, but as corbels—or, if they are insufficiently bonded, by the bonding-in of the capital itself. The shaft and its base really do nothing. They may be removed—nay, in hundreds of cases they have been removed—without the slightest injury to the work above. If "practicable" columns, actually supporting a weight, had gone out of fashion before these formal ones were used, we should naturally call the latter a survival. But as both sorts were used concurrently, we may call them an example of *quasi-structuralism*.

Things of this sort are not necessarily a sham. When a cornice has beneath it a range of dentils, each dentil is probably a survival, or an imitation of some primitive corbel. By shape and by association the corbel gives the idea of support, and without asking whether support in the present instance is actually given, we feel instinctively that the dentil course has the kind of tone and expression which suits the place. Towards the end of the 13th century the *quasi-structural* column became rarer, and other things of the same class took its place. Window tracery, which had been developed to support the glazing, was imitated on wall surfaces. Buttresses, which had been designed to hold up the vaulting, were copied in miniature on screens, and fonts, and

woodwork. The vaulting itself, on an almost microscopic scale, filled the heads of niches and similar features, where it was certainly, from its smallness, neither a sham nor a deception. And battlements, again, grown out of date as a defence to fortified buildings, lasted on as a survival in almost every belfry-tower. We need not continue the list. Whoever cares to lengthen it will find undoubted survivals in plenty wherever, from the days of the Greeks to our own, he may care to look for them. And as for *quasi-structuralism*, the insertion of structural forms where their practical use is absent, it is so universal that architecture seems hardly able to exist without it. Shall we say, then, that our art has always gone on the wrong lines? Shall we condemn every feature that lingers when its material purpose has passed away? Undoubtedly yes, if mechanical perfection is all we care for. Assuredly no, if we look for anything higher. Most things that are lovely are survivals. Their physical usefulness is gone, their spiritual beauty has come. Begun for common purposes which relate to the body, they last on for nobler ends in the elevation of the mind.

FULL OR SHORT SPECIFICATIONS.

WHETHER specifications should be short or long is a question that has lately been debated by a colonial society, and has often given rise to some doubt in the minds of architects generally. Elaborate and precise directions may, and often do, turn out two-edged instruments, and, like long letters on business matters, may become troublesome to the writer in committing him to statements he had wished he had never made. A long and detailed description of what a material or fitting or an apparatus ought to be ties the writer or architect to every item of it, for if he relaxes or slackens his demands, he opens himself to being called to account for any defect that may appear in the work, and if he exacts compliance with the letter of his specification he may, unless he is very careful and experienced, find that he has overreached himself by requiring some conditions that are absolutely detrimental and unnecessary. We have known young architects who have thus out-Heroded Herod, and have left to themselves no loophole of escape by an over-anxiety to appear clever in their demands. Many a contractor or clerk of works can tell of amusing instances of this kind of over-specifying—of requiring, for instance, concrete to be well rammed in layers, instead of thrown in, the effect of which is to make the cementing medium come up to the top—of being over-particular in the size and shape of bricks at the expense of imperfect burning; of minutely describing a bond which gives an imperfect longitudinal tie; of insisting on timber of a certain quality without specifying a certain brand, or, what is more frequent, timber from a particular port is specified, without any reference to the qualities. By his eagerness to detail minutely the brand or the make, he unwittingly exposes himself to the tricks of the trade. In timber, for example, the particular quality specified as the best may be inferior to a second quality, and unless the mode of cutting is known, few can distinguish Swedish from Russian goods. Hence a specification which provides for Russian goods of a certain quality may exclude a sounder and more evenly grained Swedish timber, and such has been the experience of those capable of judging.

Excessively detailed specifications often miss the real mark or intention of the architect; in the mass of verbiage the point of the whole is lost. Thus, a specification clause may give full scantlings of a roof truss, and yet omit to explain how the joints are to be

framed. Of course, the working drawings are to be referred to for many of these details, and therefore it is most important to explain those points, such as qualities of timber and iron, mode of framing, and other things which are not shown in the drawings. In stonework a good deal has to be explained relating to the beds of stone, average heights of stones, &c.; also as to dowelling, the material of the dowels; the running with lead of cramps; and in every branch of workmanship specific directions are more necessary than a number of general expressions which have no definite meaning, such as "provide and fix in a proper manner," or as "approved"; or details already shown in the drawings. In fact, if the specification were more explanatory and less descriptive, it would often be a better and surer guide than it is. Here we take a specification up, and find an unnecessary long preamble about the timber; that it is to be of the "best description" from "Memel or Riga or Dantzic," free from "sap shakes, large, loose, or dead knots," but not a word said about such timber to be sawn into scantlings immediately after the contract is signed. Again, to say "the ironmongery is to be of the best quality" is of no value, as every contractor puts his own idea of such an expression in his tender. The quantity surveyor's idea of specification writing is not necessarily the one to be followed, as it is generally only a repetition of the quantities, and, in point of fact, has been made up or compiled from the bill, instead of being written first. The consequence no doubt is brevity of a certain kind, but we cannot say the document is worth much. No doubt a certain amount of precision and brevity is the result of the training of the quantity surveyor; he follows a system, he takes each trade floor by floor, and begins from the beginning; he writes a preamble or preliminary clauses in which the conditions of each trade are set forth, the general directions, their details or items following the abstracts of the bill; but this leads us to the opinion that even in too great brevity there may be as much danger as too great an amplification. An easy way of writing specifications is that of commencing with descriptions of the materials, and going through the items as they appear in the dimension book.

But there is no royal road: all that we insist on is that a long clause, amplified for the sake of spinning out the specification, may recoil on the head of the writer. It must be pointed out, too, that much elaboration and minuteness ought to be followed by a corresponding fulness of supervision, for if the architect has no means of insuring that every item is strictly carried out, some busy-body or client may remind him of the shortcoming, and his own reputation for careful supervision be endangered. In some cases even his pocket may suffer from a too-anxious desire to specify items that are not absolutely necessary.

To take another instance of unnecessary detail in specifications, we often find very minute particulars given of sanitary fittings—say, a w.c. apparatus; but, from want of knowledge or experience, the writer puts himself out of court by attempting too much, as in specifying a high-priced mechanical valve apparatus, where a good wash-down type would have been preferable. Again, old-fashioned appliances, like valve cisterns of the treadle or seat action valve kind, are sometimes specified, instead of a good form of siphon flusher. Where water is scarce, a good valve-closet may be better than one of the siphon kind; but when quick-acting flushing cisterns are to be obtained, there is no advantage in specifying the more complex apparatus. In these cases an architect is more likely to get what he wants by specifying a certain type, as an "approved wash-down pedestal basin" as "Twyford's

Deluge," Doulton's or Adams' and Co.'s patent siphon cistern.

We may also study too much brevity, and this is probably the commoner evil of the two. A mere list, and often a very imperfect one, is found to do duty very often—in fact, it may be a list of items taken from the quantities. Prefixed to each is the ever-recurring injunction, "Provide and fix in a proper manner." In a late discussion, one of the speakers said he believed in making specifications as short as possible. No doubt, if it could be done with care and precision—care not to omit any necessary direction or item, and with a thorough knowledge of what constitutes good workmanship. One suggestion that has been made is that, instead of an amplified specification, $\frac{1}{16}$ in. scale detail drawings "be prepared of every part of the building which cannot be described or specified in simple language and few words." Contractors would understand it better than a long specification. No doubt they would, and the architect can express in a few lines his ideas better than he could verbally describe, especially the style of work intended and the construction proposed. The objections entertained by architects to supply numerous detail drawings, are that they often lead contractors to increase their tenders, and that in case of abandonment of the work they would be all thrown away and their labour would be lost. Further, the specification affords a convenient means of completing the architect's design without committing himself to details that might not be suitable, and, in fact, the same objection may be raised against amplifying drawings or making them minute, as against detailed specifications.

We do not see, however, why specifications should not be more amply illustrated by marginal sketches. Many a descriptions of stonework, carpenters' and joiners' work, and other trades could be made quite clear by a sketch or diagram. Take, for instance, roof-framing: any particular joint or connection might be simplified by a sketch, which would render a lengthened explanation unnecessary. A piece of framing or the kind of moulding is at once grasped by a sketch, however rough it may be, and would prevent the affixing of a fictitious price in the tender. Unfortunately, the indefinite and verbose description encourages the habit of making guesses either in excess of what is required, or a great deal below the mark. A vague specification of a staircase may, for example, mean a considerable difference in the amount of tenders. Hence, while elaboration and minuteness of description ought to be avoided as tending to implicate the architect, and likely to be used against him, on the other hand, vagueness and commonplaces can be of little practical use whatever. No doubt the primary object of such a document is to explain those details of a building or its construction that cannot be clearly illustrated by the drawings, to specify, define materials or scantlings, and modes of execution; and for this reason it should be prepared by the architect himself, and not left to an assistant, who, by the aid of an old specification, manages to draft what is required. The subject is one that the architectural societies may take up with advantage, and it may be worth while to award prizes to students for compositions of this class, to be founded, of course, upon actual designs.

ARCHITECTURAL ASSOCIATION.

THE second meeting for the present session of the Association was held on Friday evening, the President, Mr. H. O. Cresswell, in the chair. The following 48 members were elected:—F. S. Short, H. H. Skipper, Cyril Power, T. F. Green, G. H. Smith, G. P. Sheridan, W. H. Barrett, A. E. Gardner, F. E. Morris, A. H. Allan, S. P. Brinson, J. S. Lee, P. E. Stenning, E. G. Page, A. Stedman, A. F. J. Cox, C. A. J. Shar-

man, A. J. Gurney, T. E. Abbott, P. G. Redgrave, B. Hoole, J. H. W. Lake, R. S. Y. Fowler, A. G. Bewes, T. Wallis, F. Lishman, M. G. Pechell, P. Morris, W. H. May, G. O. Scorer, P. Sherrin, M. F. W. Bunney, A. B. Hayward, C. R. Hicks, E. Wheeler, W. J. Waghorne, J. E. C. Shield, J. P. Bishop, G. B. Hoole, C. D. Gruchy, S. Perkins, A. E. Dainton, A. W. Pocock, J. H. Coram, J. L. Walker, F. C. Simpson, E. C. Nisbet, and H. E. Y. Haggard.

NOTES ON THE APPLICATION OF ARCHITECTURAL EDUCATION.

A paper on this subject was read by MR. WILLIAM YOUNG, F.R.I.B.A., of London and Glasgow, who mentioned that hitherto he had uniformly declined all invitations to lecture, but could not refuse the request of the secretaries of the Association. When I read over your curriculum for the present session, I was impressed, he remarked, with its comprehensiveness. I thought of the time just past when every architectural student had to work out his education in his own way, and I wondered how men like Wren and Inigo Jones acquired their architectural education, without even the aid of the splendid architectural libraries now at our service, and with very little instruction in drawing. The student now has his course mapped out for him, and facilities are given him which were never within the reach of students of architecture before. Great credit is due to this Association for this good work. You have given us, or are giving us, the training and the knowledge, the art and the power, whatever you like to call it, to design buildings, make plans, and write specifications. But the difficulty of realising our designs in brick and stone remains undiminished. The most difficult period in an architect's career is when a young architect begins to turn his education into practice. Remember, I only say it is difficult, not an insurmountable difficulty. Indeed, some of you may get over it as easily as you passed over the *pons asinorum*. Some of you may be born into the way of practice, some may be thrust into it by kind friends; but with zeal and energy all of you may forge your way into it. An architect's education is never complete. For every true architect, his education is always going on, and that is what gives the man who has been a long time in practice, and done a lot of work, such an immense advantage. He has an education which only comes by doing much work. It cannot be got in any other way. When you begin to practise you will find the advantage of the education you are receiving here. Have your mind well stored with knowledge, you can make use of it all in the practice of architecture. Know something of everything, and everything of something. That is the ideal education for an architect. But don't lose sight of this fact, that after all education is only the tools with which you are to work. And we judge a man by his work, and not by the tools with which he does it. And it is not the tools you possess, nor any ornamentation in the way of letters after your name, no matter what those letters are, that will make your position as an architect. It is not even reading papers, or giving lectures, or taking part in discussions, or writing letters to the papers that will make your position as an architect. No; it is your work, and your work alone. As a good tree is known by its fruit, so a good architect is known by his work, and by his work only. At the commencement of a career, many of you may look to competitions as one way of applying your education. Many young men beginning their career as architects regard a competition as a short cut to success. That idea, let me tell you, is all romance. It would do very well for a novel. An author, if he should happen to make his hero a young architect, would probably make him enter some large competition, for some great public building, and he would get the first premium awarded to his hero, making his design far and away above all the others, leaving the older architects nowhere, but filling them with surprise and envy at the splendid achievement of the youthful hero. No doubt this would go down in a story-book; but that novelist would not be a realist. His picture would not be true to life. No, there is no such thing in the real life of an architect as jumping at one bound to the top of the tree; as in everything else, there must be time for growth. So your probabilities of success in

competitions will be much greater after you have had two or three years' experience in carrying out buildings; your designs will then take a practicable and realisable form that they would not have without this experience. Although I am not a believer in competitions, they are an established custom, for the present, which we have to face, and I am not going to say anything that would discourage you from competing. But let me say, I believe you might count all the men who have made a position for themselves by competition on your fingers. Few have gained by them, and architects, as a body, have lost by them. Look for a moment at a competition from a financial point of view. Let us take one for a building to cost, say, £20,000; twenty-five designs are sent in, and probably a good many more begun and not sent in. Each design would have about ten drawings, and you may put down the minimum out-of-pocket expenses at £40. Take 40 by 25, and you will find the twenty-five competing architects have spent £1,000 in order that one of them may earn a commission of £1,000. It is not as if the successful architect took the £1,000 for the competition drawings. No, he has still to make all the working drawings, &c., to earn his commission just as if there had been no competition. A commercial man would say: This may be art or it may be profession; but it is not good business. But there is a much more serious objection to competition, which is this: After you have taken every possible pains, and expended skill and labour, not to mention money, and really have produced a design of high merit, you have to face this fact:—That in competitions generally the gate of success seldom swings on the hinges of merit. It is a startling statement to make; but it is a fact. It is for this reason, amongst others, that my advice to you is this: Put not your trust in competition, for the ways thereof are dark and doubtful. Use them, if you will, but only as an extra string to your bow, if you use them at all. If you will compete, use great discretion as to the competitions you go in for. Don't attempt a subject you have no experience in; wait until there is one you understand. The planning of many classes of buildings, such as hospitals, lunatic asylums, and workhouses, is the result of a development by specialists, and you could not make yourself thoroughly acquainted with the subject in the time allowed. Don't attempt too much or too many, and stick in the middle. I have known many promising young men who were always beginning things and completing nothing—they were failures on that account. It is a wholesome rule to complete anything you put your hand to—try it, and you will find out its value. Don't give all your thoughts to the elevations to the neglect of the plans. Be strong in your planning if you mean to win. Don't send in scamped and anyhow kind of drawings for the plans and sections, and beautiful drawings for the elevations. Don't compete where the conditions are mean or unfair, and avoid all competitions which announce three premiums, and in a little note at the end inform you the first premium will merge in the commission; as a matter of fact, it is only two premiums, not three, and the promoters should honestly say so. Some committees think that architects will accept any conditions they choose to impose on them. If architects were united, as they should be, all this would soon be changed. Don't make a design that would cost double the sum stated; an assessor is bound to throw it out. In short, prepare your design and your drawings as if you were going to be saddled with the responsibility of carrying out the work. One of the best things to know about competitions is to know when to avoid them. On the morning after the result of every competition is made known, there are many men sorry for having competed. Perhaps sorry would be too mild a word to express the feelings of some of them after they see the accepted design; but if you were to poll the country over, you would probably not find one man who was sorry for not having taken part in the competition. The most interesting individual for you when you commence practice is a client. There are two classes of clients—the private individual and a public body, represented to you by a committee. There are, of course, infinite varieties of both, but they both require management, in the sense of understanding them and their wants (for what they want and what they ask for are often two different things), so as to be able to guide them and get on with them, some-

times a very difficult and delicate thing to do, and requiring a great deal of judgment and sometimes much patience. It is a simple enough thing to do when you know how, but as the way of doing it is not taught in the classes, you will only come by it by experience. Some men have the gift intuitively. Some never acquire it, and, in consequence, instead of going on smoothly and pleasantly with their clients, and becoming friends, it is all the other way—disagreement and differences and dissatisfactions. On such terms the game is not worth the candle. The great thing is to get your client's entire confidence, and the comprehensive education you are pursuing here will help you, in a large measure, to this end. For clients ask all kinds of questions, on every conceivable subject, and you are expected to be able to answer at once. If you cannot, they think that you are not so well informed as you ought to be. You will find that some amount of foreign travel, and a personal acquaintance with some of the principal buildings in Europe, both ancient and modern, and also of these in our own country, will be of much service to you in gaining your client's confidence, and immense service to you in your work. This necessity of having your client's confidence and being able to manage him, or, in other words, advise and guide him, is the more necessary, for you will find in many instances, probably in most, if you want to carry out good work it is not enough to be able to prepare good designs. You will also have to persuade your client to let you carry them out unmitigated. If you have a special feature in your design—one on which you pride yourself for its originality and go, it is almost sure to be objected to on the score of expense, or simply because it is original, and they don't like it; and it will depend on your judgment and tact to bring your client round to your views. A good many buildings are ruined and good designs spoilt by the architect having to give way to his client. Committees, I was once told, are the most difficult clients to get on with; my experience is all the other way, I think they are excellent clients to get on with. But you will require some acquaintance with the rules of procedure in committee. This is important for you to learn, for committees are strict as to rules of procedure. See that everything decided upon is put in the minutes, and have a copy of every minute sent to you. If the work you are engaged on takes a long time, the committee at the end may be entirely changed from the one you started with, and you may be the only one left who knows what has taken place; and your acquaintance with the minutes, &c., will keep them right. They will look to you to do so. If you do not get on with your committee, you will have a bad time, for then comes in the truth of the saying that "a committee has no soul to be saved." Avoid making speeches in committee—they look upon that as their prerogative. Say what you have to say in a few words. Be always in touch with the chairman; he has usually a great influence over the other members, and is expected to know everything. Don't take a committee by surprise. If you want anything important—an extra £20,000 or so—don't throw the request like a brick at their heads. Talk things over first with the chairman and two or three others. You will find that most important business in committee is pretty well agreed upon before it comes formally before the meeting. If your committee take a wrong view of a matter, or are likely to divide in place of being unanimous, get the matter put off until another day—what you want will then probably come all right. Committees have immense powers, and when they once come to a decision it is almost impossible to get them to alter it. With committees, as with private individuals, you will find that with a little tact, and being always straightforward and open, and especially being yourself strong—with sound reason and clear—as to what you want to do, you will generally succeed in leading your client to do what he ought to do—or, rather, to let you do what should be done. But if you are undecided yourself, have not fully made up your mind, if you are vacillating and uncertain, then depend upon it your client will often make you do things that will be no credit to you and be no satisfaction to him, and they will blame you for it. And, by the way, let me add emphatically, if you want to manage them, never put on what is called "side." It is detestable under all circumstances, and would at once put a committee against you. If

you manage well, you will find that many a man whom you meet at first only as a client becomes your friend for life, and this management of clients is worth taking trouble over, if you consider that the one object of it is to enable you to do better work—to save your design from being cut down and spoilt, and so far promoting the practical advancement of architecture. For remember this—one good work does not remain alone, but leads others to do good work. It was said in this room, and it has been said elsewhere, that after all architects were the servants of the British public, and you will have to give them what they want. Well, I admit we are the servants of the British public, but we will best serve them by giving them what they ought to have and what is best for them. If men come and give you a commission to carry out fads and impracticable notions, or schemes which you know to be wrong, and which, if carried out, would be a disappointment to them and no credit to you, then the only true way to serve the British public is not to give them what they want, to oppose them, but to do something more: to show them where they are wrong, and even persuade them to do that which is right. This, in my opinion, is true service, and should be paid for double commission. I have known instances where it took almost as much of one's time to keep a client from going wrong as it took to do the drawings of what was carried out. I am not advising that you should take the high-handed course of opposing every suggestion that is given to you by your clients; on the contrary, I think the wise architect is not so conceited as to think no one has good ideas but himself; and he will take any suggestion, if there is any good in it, from whatever source it comes, and apply his skill to lick it into shape. We are not an artistic nation; the public are not hungering and thirsting after art in building; but they will thank you afterwards for giving it to them, even although they may oppose the doing of it. Let me give you a little illustration of this. I was once engaged on a large public building, and the work had so far advanced that we had to come to the staircase. It was a big one, and capable of being made a grand architectural feature. You will often find that your best opportunities for applying your art is in the interior of your building, and you will have to make the opportunities for yourself; they will seldom be offered to you. To carry out my idea I asked for some £15,000 or £20,000 to make it a marble staircase. This was staunchly opposed by some on the ground of cost. It is quite unnecessary, said they; a good, easy, stone stair, with a handsome cast-iron railing and plaster walls is all that is required, and will look very handsome and spacious. What do you want with marble steps and balustrade, and marble columns and walls and floor? It is extravagance and waste. Well, I got what I wanted, and in time the staircase was completed, and done in a way and at a cost far beyond anything the committee had ever seen or contemplated having. Soon after the work was completed I was present one evening at a reception, and met one of the leading opponents to the work, a staunch economist, on this very staircase. He came up to me with much friendly enthusiasm. "Mr. Young," he said, "this is grand. I had no idea you intended giving us anything like this, or I should not have opposed it for a moment. We are all proud of it; every ratepayer is proud of it, and not one penny of cost is grudged." In this instance people got what they wanted, not what they asked for, and I have no doubt that they would have been quite satisfied and found no fault with me if they had got instead the stone staircase with the cast-iron railing. Your first work you may regard as the foundation-stone of your future success. If it is well designed and well carried out—the one will be no use without the other—it will bring you another, and the next may bring you two, and so on. If your first work is not a success you will have missed one of your best opportunities. How are you to make it a success? First of all, let your design be thoroughly practical—we live in an age when the practical is put before everything, and is better understood and appreciated than the artistic. Notwithstanding this you should try and be something more than only practical. Try and infuse something of the spirit of art into your work. For there is no doubt that such work is appreciated by some people when it is done, and will tell in your favour. There is a kind of

erroneous notion abroad at present that if an architect is practical, he is not artistic; and that if he is artistic, he is not practical. Let your work show that you are both practical and artistic. A man may be thoroughly practical, and with all his efforts he may not be able to put any artistic feeling into his work. It is no fault of his. But if you have the gift of artistic conception, it is entirely your own fault if you are not practical, for practical knowledge may be acquired partly in the classroom, but more in the office and the workshop, and mostly on buildings in progress. It is this combination of the practical man and the artist that will make your work a success. Besides knowing everything about good and bad material, and good and bad workmanship, your client will expect you to know all about the proper cost of his work, and it is reasonable that he should do so. An architect should always know what his work should cost, and his estimate must be very loose indeed if he cannot find a first-class builder to do the work at his estimate. Sometimes even surveyors may go wrong, and it may be necessary for you to look after them. Some years ago I had a mausoleum to build. It was a small thing, a Greek cross on plan, with a dome, and all in stone. The estimate came in about £4,000, which was much more than it ought to be. I looked at the prices, they were not unreasonable. I, at last, got the total amount of stone in the estimate, which seemed enormous. The fault was here. So I sat down with the surveyor and went through every stone. I happened to be quite as well up in masonry as the surveyor, and the result of this was that the estimate was brought down to something like £3,000 without altering the design in any way, and the work was done. It is not interesting work, but your clients will, above all things, expect you to look after the cost of things, and advise if it is fair or not. You should have an eye to this in your education. I think myself that estimates and accounts are the *bête noir* of an architect's life. They hamper you with your designs when you are doing the work, and they come back to you when the work is done, and you want to forget all about it. But nevertheless, you will find it much to your advantage to be well up in the cost of things. "Keep within your estimates" was the advice given to me when I was commencing practice by an architect who was doing a large amount of work; "that," he said, "is the way I got on. I got a name for always keeping within my estimate, and clients came to me on that account." It was excellent advice, and I pass it on to you. Years afterwards, in conversation with one of the most eminent civil engineers of the day on this same subject, he said: "If we want an extra £100,000 for structural purposes we get it, for no company would take the risk of failure, after the request." That was also a useful hint, and I pass it on to you. On no account avoid asking for an extra, if it is necessary, for foundations or any structural purpose. But, apart from all this, there are times when an architect is building for the future as well as for the present, when cost must be a secondary consideration, when the first and only duty is to do the work thoroughly well. This occurs mostly in large public buildings, but also sometimes in large private buildings. Such opportunities are not to be missed or misused by questions of cost. You may save a few thousands, and spoil your work, and the generations who come after, and who have to pay their share of the cost, will blame you for not doing the best. Cost is only a question of a grumble of a day or a year—good work is appreciated for ever. As well as being a servant of the British public, a true architect is also a servant—he should be a disciple—of the great art of architecture, which is neither English nor French, neither German nor Greek. It belongs to all countries and to all ages. It is neither Classic, nor Gothic, nor good Queen Anne; but all of them, and much more. Its aim and mission is a large one. It is not to put up a beautiful building here and there, but to make every building beautiful, both without and within, and to make all the surroundings of life beautiful. Why should not every building in every street be beautiful, and the streets and the squares themselves made beautiful and pleasant places? It is not an impossible idea—it is not even an extravagant one—and in time I believe it will be done. It would do more to make people happy than an eight hours day, and it is quite as attainable. Apply your architectural educa-

tion to bring about this end, not only by putting up good buildings, but by your influence becoming in a way missionaries of your art, to teach people to love the beautiful, and create a demand for it. This is another way of serving the British public. In all your work take utility for your friend, and practical knowledge for your companion; but let the beautiful be your only love. With this triple association, your works will serve all the useful purposes for which they are intended, and they will possess all the elements of stability and endurance, and, being pervaded with the highest quality, the beautiful will appear in them everywhere. Take with you to light you in the way of practice, all the Seven Lamps of Architecture. Take the Lamp of Sacrifice, the Lamp of Truth, the Lamp of Power, the Lamp of Beauty, the Lamp of Life, the Lamp of Memory, and the Lamp of Obedience. But I am going, as a practical architect, to suggest to you a new lamp, which has served me, and will probably help you on your way—the Lamp of Enthusiasm. Older and perhaps wiser men will say,—No, no; don't recommend these young men enthusiasm, give them rather perseverance. Well, perseverance is a very good thing, and indispensable, but perseverance is cold and enthusiasm is greater, for it is perseverance with love added, and you will do no good work without love for your work. Perseverance may make a surveyor, but it takes enthusiasm to make an architect. Light up the Seven Lamps to guide you with your work, but illuminate your drawing-board and your mind with the light of Enthusiasm. It will help you over difficulties, and will sustain you in days of doubt and depression, which come to all men, and especially to men of artistic temperament. If I were asked to put in one sentence how best to apply your architectural education, I would say: Preserve your enthusiasm for your art. By this means you will best apply your architectural education. By this means you may advance the architecture of the day in which you live, and by this means you may be enabled to add your own contribution to the architectural monuments of the world.

Mr. E. W. MOUNTFORD proposed a vote of thanks to the lecturer, remarking that he had had some little experience with competitions, and thought that if a man went into them enthusiastically, and with some thought, he could not go far wrong. When a young man commenced practice he was not overburdened with commissions, and he did well in that case to try his hand at a competition or two; he was certain, if he put forth his best efforts, to gain experience in some one subject, and was the better prepared for paying work when it came, even if he never won a competition. In most competitions, however, there were a large proportion sent in that never had a chance of winning; he should say that 75 per cent. were so feeble that one wondered why they were sent in. Taking it all round, there was not much to complain of in competitions as now conducted with assessors, although a glaring case occurred in South Wales recently, where the author of the premiated design was superseded in the job by a local man, who offered to carry out the town hall for 4 per cent.

Mr. J. M. BRYDON seconded the vote of thanks, which was supported by Mr. SIDNEY VACHER and Mr. E. S. GALE, and carried by acclamation.

Mr. YOUNG, in acknowledging it, said that perhaps he might some day give a lecture, as had been suggested, on "How to get Clients"; but he should be compelled to charge a guinea a-head to those who heard it.

HEREFORDSHIRE NOOKS AND CORNERS.

MR. H. THORNHILL TIMMINS has issued a well illustrated and popular handbook of Herefordshire, and Mr. Elliot Stock has published the work,* with a terse introduction by Canon Phillott, who, naturally enough, rejoices in the quiet of his little-travelled county, possessing no manufactures and not many commercial attractions, lying as it does out of the way of the ordinary traveller. The nooks of scenery, wood and water; nooks in architecture, domestic and ecclesiastical; and nooks peculiar to the unsophisticated rural life of the Herefordshire native, have all charms of their own, dear

to the artistic mind, and Mr. Timmins has given us a reliable guide which may well serve as an inducement to those who know the county only slightly to increase an acquaintance with it in the pursuit of the noble, lovely, and picturesque. Herefordshire, stretching from the shelter of the Malvern Hills to the Black Mountains of Wales, is watered through the Forest of Dean by the Wye, which breaks its way to the sea by the rugged gorge of Symond's Yat. To the north the river Teme tumbles along amidst picturesque scenery, and soon to Ludford, Ludlow, and Shropshire. The broken and hilly character of the fertile lands of the county of Hereford presents an almost endless variety midst every change of prospect over the water-meadows, orchards, hop-gardens, corn-fields, and clumps of forest trees in the richly-wooded landscape, where

"No spring nor summer beauty hath such grace
As I have seen in one autumnal face."

The city of Hereford is situated almost in the centre of the county, and thus forms an admirable starting-point for exploring the district in any and every direction. Mr. Timmins gives us several views, descriptive and pictorial, of the city and its cathedral; but one special value of his book consists in his taking the reader to outlying and comparatively unknown spots, instead of packing his pages with materials most ready to hand, such as those concerning Hereford itself and other of the more familiar spots. His drawings are fairly well represented by the selection which we print to-day from the original blocks. These, by way of being the more interesting to our readers, are exclusively of old buildings; but in the volume itself will be found some sketches of a more pictorial character, representing the scenery and other local details, and facing the title-page a capital map is provided, showing the county at a glance. We have devoted so much of our limited space to illustrations from Mr. Timmins's book that we are prevented from following him through his descriptions generally so closely as we should otherwise wish to do, and, therefore, must confine our remarks more particularly to the subjects represented in his accompanying sketches. The Grange House at Leominster, hard by the recreation grounds, is now a private dwelling, and is a reconstruction of the old market house or "Butter Crosse," which was thus rescued from destruction by Mr. J. H. Arkwright, of Hampton Court, which lies a few miles nearer Hereford. It is one of the best specimens of the handiwork of that famous 17th-century builder, John Abell, whose other houses of a similar kind at Hereford, Weobley, Kington, and Brecon have unfortunately been razed to the ground. The building is carried upon twelve stout oak posts, treated as columns, with Ionic caps, with brackets and arched timbers. Along the head pieces an inscription is carved, written partly in English and partly in Latin, with the date 1633.

Prior's Moor lies out of Hereford over the hills past the White Cross, which is a memorial of the time when the plague visited Hereford, the town's market being held here then instead of in the stricken city. The pink-washed walls of the old farm house and pigeon-cote make a brilliant contrast with the blue sky beyond, and harmonise well with the timber framings and the brickwork.

On the high road between Kington and Presteign, just within the county border, stands Rodd manor-house, with its wide mullioned windows and doorway set deeply within a massive arch. It is a pleasing example of brick and stone building, picturesquely covered with creepers and ivy mantlings. Inside "The Rodd" is very little altered. The rooms are panelled with oak, and have oaken floors and big, low-proportioned doors, furnished with the original hinges and latches in solid frames. The principal apartments are wainscotted from floor to ceiling, and contain two handsome chimneypieces, the lower one bearing the arms of Rodd and Price. We illustrate one of these fireplaces. Adam and Eve, accompanied by the serpent, which enriches the central pillar, form the subject of the "Temptation." The jambs are composed of two Jacobean-dressed men, both bearing the left arm in a sling, while the pointed beard of each is grasped by the other hand, suggesting the conjecture that thereby "hangs a tale." The Rodds (Rodes or Royds) are an ancient family, and this old manor is their historic home. Sir Hugh de Rodd distinguished himself at the battle of Ascalon, in Palestine, in

* "Nooks and Corners of Herefordshire." By H. THORNHILL TIMMINS. London: Elliot Stock, Paternoster-row.

THE RODD.

WEOBLEY.

the days of Richard I.'s crusade against the Saladin.

Weobley is a village of the veritable "Sleepy Hollow" character, but its handsome church

and charming old houses bear witness to its more prosperous bygone times when it returned two burgesses to Parliament. In Leland's days it was a market town, and had, he says, a goodly

castle, belonging to "My Lord Ferrers." The market house, erected by John Abell, has been destroyed, like the castle. In the main street are several old timber houses, and one formerly the

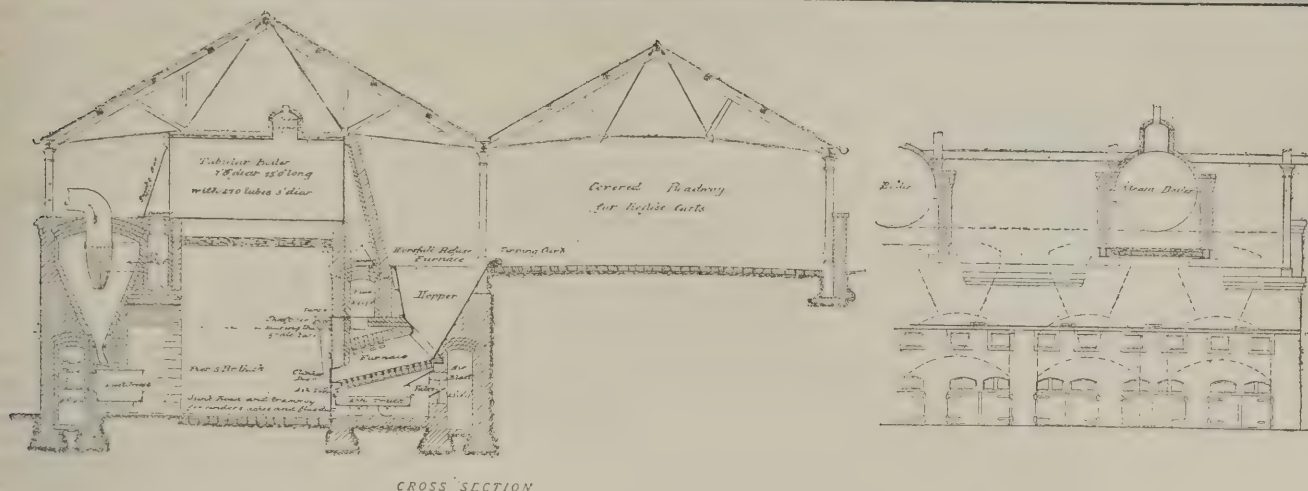

abode of one Tomkins, whose exploits are recorded in a sonnet written to his honour, for "he was the father of thirty-two children, born in one chamber at Weobley." We illustrated the old schoolhouse porch in the *BUILDING NEWS* for August 28, 1891, and herewith we print a view of one of the streets, with the church spire over the trees in the distance. Mr. Timmins gives several capital sketches of the place. The pigeon-house at Buttas belonged to the farm property erected near Wormsley, the site of an Augustinian priory, and was built by George and Elizabeth Kauer in 1632, and was locally known as "The Falconry." This quaint little building is the handsomest of its kind in Herefordshire, and is richly decorated with running foliage. It stands in an out-of-the-way place upon an eminence, by the side of the farmhouse, overlooking a fine landscape bounded by the Malvern Hills, which can be seen on a clear day. Among the other subjects illustrated in the book before us are Abbey Dore Church, Kilpeck Church, Treago House, Fawley Court (near Ross), Cradoc House, Sellack Church, Ross Market, Rudhall Manor, Goodrich Castle, Wythall Farm, and Croft Castle. The volume is nicely got up, and, besides being a capital drawing-room book, will make a useful addition to the architect's collection of topographical handbooks of a reliable architectural character. No better evidence of this need be wished than the illustrations given by us with this notice to-day.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE inaugural meeting of the present session of the Institute was held on Monday evening, when there was a large attendance of members and their friends, including several ladies. The chair was occupied by the President, Mr. J. MacVicar Anderson, who delivered his opening address. He remarked that we lived in an age of progress, and that this element was the characteristic of a living age. Not all the changes and reforms of modern times had advanced civilisation, and he was assured that some at least of the changes with which society was now threatened would fail in attaining the results professedly desired by their advocates, and would end in disappointment, if not disaster. In a review of some aspects of the profession, he was struck with a remarkable development of recent years—the perfection which architectural draughtsmanship had attained. It was not possible to regard the drawings submitted yearly for the prizes offered by the Institute and the Royal Academy, or prepared in profusion for competitions, with anything short of admiration, combining as they did technical accuracy with artistic feeling—the essential characteristics of good draughtsmanship. To set side by side the drawings of some generations since and those of to-day, was to exhibit not so much comparison as contrast; for in many drawings of old masters in architecture knowledge of perspective and firmness of touch were alike conspicuous by their absence. The perfection of modern draughtsmanship was, no doubt, to be traced to some extent to the spirit of emulation inspired by competitions for students' prizes, and to the prevailing practice of inviting competitive designs for public buildings, both of which enlisted all the resources of the draughtsman's skill. That this advance in architectural draughtsmanship constituted, so far as it went, real progress might be conceded; indeed, the younger members of the profession might be honestly congratulated on the artistic beauty and perfection of their handiwork. If, therefore, he pointed out a temptation to which their skill exposed them, he did not desire to detract from the legitimate merit of their work. No one could doubt the importance of good draughtsmanship to an architect, for it enabled him to express readily and freely the ideas which were to constitute his design. The pencil was to the architect what the pen was to the author—the mode of expressing his ideas; no more. Essential as this was, obviously the mode of representation was of less consequence than the thing represented, and it was because he had observed a tendency to drown architecture in mere draughtsmanship that he reminded his hearers that, although every architect ought to draw, and draw with facility, it was yet possible to be a good architect without being a brilliant draughtsman; and, conversely, that it was possible to be an expert draughtsman,

and yet not to have any claim to be an architect. Architecture was the material embodiment of conceptions of the mind: drawing was the medium by which these could be, at the best, but inadequately expressed. It might be excusable to smile at the draughtsmanship of old masters whose names lived in history as great architects; but it might not be amiss for the brilliant draughtsmen of to-day, while justly proud of their attainments, to ponder on their prospects of acquiring equal fame; for while it was good to know how to draw with artistic excellence, it was better to know how to design with purity and truth. In architectural competitions the importance of appointing professional assessors was often enforced on the ground that it was impossible for promoters to arrive at a just decision without the assistance of an expert. This was true; but there was another side to this question—viz., that not the least responsible part of an assessor's task was to protect promoters from being imposed on by the tricks of draughtsmen whose ability was more apparent than their morality. Such trickery might mislead the uninitiated; it was transparent to the expert, and at the hands of a just assessor it would not fail to meet with a just reward. Touching next upon architects' education, the President raised a laugh and cheer by remarking that Modern Progressivism had not reached the stage of proposing that free education should be extended to students in architecture; and the risk of over-education, therefore, was one to which they were not as yet exposed; but, apart from such a Utopian prospect, which might be in store for their posterity, the educational facilities which students now enjoyed were remarkable when compared with those of a generation or two since, and especially so the latest developments exhibited in the remarkable curriculum of University College, King's College, and the Architectural Association. The new departure of the latter body was regarded by not a few with some amount of apprehension; but the progress attained during the first year—necessarily the most trying and critical—had been real, and such as to encourage the promoters in the continued and energetic prosecution of the scheme. The scheme now under consideration of creating architectural provinces, each with its own centre, and embracing an area with defined boundaries, would certainly tend, by stimulating local organisations, to facilitate the attainment of systematic educational organisations throughout the country. To what extent architectural education was likely to be affected by the proposed establishment of a Gresham or Teaching University for London could not be predicated. That such a university must embrace art, as well as science and literature, might be taken for granted, and it would seem reasonable that a definite place should be claimed for architecture. Teaching naturally suggested examination, and as to this he would remark that no advocate of examination ever thought or expected that it would or could create a great architect. It was not fair criticism to condemn an educational test because it did not effect a result which was never intended, and which was impossible. As consistently might University tests be objected to because they did not in all cases produce great divines. No one disputed the point that they acted as stimulants to the acquirement of knowledge upon which success in life so largely depended. The Associates' examination had hitherto successfully withstood the somewhat fierce—and not always just or fair—criticism to which it had been exposed, for as a practical issue, the rising generation of architectural students had come forward in increasing numbers, and the cry was, "Still they come!" Did not that imply that they appreciated the active labours of the Institute in endeavouring to raise the standard of knowledge and promote the efficiency of architects, rather than mere academical and inoperative disquisitions? The examination might, perhaps, exhibit defects of organisation, or might be capable of improvement in certain particulars, but that, after all, was no more than might naturally be looked for in a comparatively new institution. The examination continued to prove an encouragement to study and a stimulus to the increase of knowledge, and thus had been a step in the direction of real progress. He would remind architects that the examination would be conducted in its present form until the end of 1893 only, and that thereafter the progressive examinations would be in full operation. As to the proposed examination or qualification for Fellows, he thought that

all were now convinced, whatever might be their individual opinions as to how the change should be effected, that some change should be made in the qualification for Fellows. It would be inconsistent and intolerable were the present position to continue, for it meant that up to thirty years of age men could only be admitted to membership by passing an examination, and that after reaching that age they could be elected Fellows without any such test. This was never intended to be a permanent arrangement, and had only to be stated to secure condemnation. Mr. Charles Barry's proposal, now under consideration by the Council, that candidates for fellowship should, with certain exceptions, only be elected from the class of Associates, would practically be equivalent to applying the same test to the primary and secondary classes of members, and did not seem to the President sufficiently to meet the case. Then, again, others considered that the qualification for Fellowship should be a separate examination on a higher grade than that for the Associateship. To that the reasonable objection might, he thought, be raised that men would thus be called on to undergo an exhaustive and trying ordeal at a time when they were likely to be engrossed with practice, and would not, therefore, have leisure to prepare for it. Personally, he thought that the further test or qualification for Fellowship should be, in addition to what now existed, an examination of the actual work of the candidate. He would say, let an Associate be tested as a student; let a Fellow be tested as an architect. To carry this out, it would only be necessary to enact that on and after a date to be specified, every person desiring to be admitted a Fellow should, in addition to the present qualification, be required to have passed the Associates' examination, and to undergo the further test of submitting to the Council evidence of his executed works, always providing for special or exceptional cases by the dispensing power which the Charter conferred on the Council. What better or more fitting test could there be? for by his works the architect was known and judged by the public. It might be objected that this would be subjecting an architect to examination on what, after all, was a mere matter of taste. He thought not. Architecture was much more than a matter of taste, and if this test were applied, it would be a test of architecture. The Council of the Institute was composed of individuals each one of whom had his own idiosyncrasies and preferences, and his own conception of what constituted good architecture; but the collective body would ever be the representative, not of a school or a party, but of the profession of architecture, and he could conceive of no adjudicatory court likely to prove so fair and so competent. He hoped that the Council might see their way to present a unanimous recommendation on this subject, and that after full discussion the Institute might also arrive at a unanimous decision as to the best solution of the problem. The President, having referred in terms of regret to the resignation by Mr. Aston Webb of the office of honorary secretary, which he had held for more than three years, expressed his pleasure that Mr. William Emerson had consented to serve if elected, and as his was the only name submitted he would be proposed for election at the business meeting to be held a fortnight hence. The great question of Capital and Labour, the President continued, is one which we architects cannot disregard. Capital and Labour are alike essentials to the execution of our designs; without them we could produce pictorial representations, but not buildings. Labour may be congratulated on the manifest desire now exhibited by society to accord to it fair, and even liberal, remuneration. That this may to some extent be attributed to the stand which workmen have by combination and organisation made in defence of their interests, may be fairly conceded. To combination for such legitimate objects no reasonable person can, or does, object; but when trade organisations are used for the purpose of imposing arbitrary restrictions on labour, of depriving the workman of his right as a free citizen to work how and as he pleases; or of arbitrarily reducing the hours of work without a corresponding diminution of wages, such as may be dictated by the law of supply and demand, then it seems to me that the real friend of the working man is not his leader who preaches such pernicious doctrines, opposed alike to political economy and common sense, but rather he who bravely warns him of blind leaders of the blind.

CROSS SECTION

who, be their motive what it may, are luring him to inevitable and certain disaster. When last year I was—as your representative—invited to settle by arbitration the differences that then existed between the master builders and the carpenters of London, I did not hesitate, when making the award, to record my conviction that the result of such action had been to inflict permanent injury on workmen by driving their trade into foreign channels, from which it was not likely to return. That this has occurred there is abundant evidence to show. Having referred to the projected new thoroughfare from Holborn to the Strand, and criticised the direction of the thoroughfare at its southern extremity, the President continued: In their report, the committee of the London County Council state that the plan which they recommend would enable “the Council to control the architectural elevation of the new street.” Should this mean that the control is to be real—and not visionary as in the case of Northumberland-avenue—and that it is to be exercised by persons competent to deal with the subject, we may regard the proposal with satisfaction; for, under such conditions, architects need not dread irksome interference with their designs, but those who claim to be so without justification would be properly subjected to control from which the public could not fail to derive benefit. It is to be hoped that architects who may be consulted may be inspired by no lesser motive than the endeavour to educate public taste by adorning a public thoroughfare. Our teaching is not that of a book or a parchment, which may be read or cast aside, nor that of a picture, which may be studied or disregarded at pleasure, but it is engraven in a material form which must be seen and read of all men whether they will or not. Would that architects who undertake to design buildings for important sites and leading thoroughfares always realised that they incur responsibility, not to their clients only, but to the public also. Speaking generally, for there are exceptions here as elsewhere, who will say that the structures in Shaftesbury-avenue adorn it, or create emotions in a cultured mind other than those of irritation and disgust? Buildings they are certainly—architecture they are certainly are not. Take another illustration. Who can imagine that the authors of the edifices which have recently been erected on that magnificent thoroughfare the Thames Embankment between Waterloo and Charing Cross Bridges, or at Albert Gate, realised this responsibility? We hear much said, and we see much written, of the necessity of educating public taste. But, while this is too true; while splendid opportunities are absolutely sacrificed which might have been and ought to have been mediums for elevating and refining public taste; yet when I recall the depressing dreariness of an age of stucco and monotony now happily a thing of the past; when I behold the advent of an age distinguished by the use of genuine materials; when I appreciate the artistic spirit which unquestionably breathes in much of our domestic work; and when I recognise the undoubted desire of all—whatever their shibboleth—to promote the knowledge of our art, whether by study, practice, examination, or æstheticism, I gladly record my conviction that the architecture of to-day—although falling far short of what we long to see, although exhibiting

an exaggerated enthusiasm for the element of quaint picturesqueness which I hope at no distant date to see leavened by the spirit of classic purity and simplicity—is yet not altogether unworthy of the enlightenment of these latter days, nor altogether out of harmony with this age of progress.

A vote of thanks was accorded the President by acclamation on the motion of Mr. Eustace J. A. Balfour, seconded by Mr. Paul Waterhouse, and supported by Mr. H. Hardwicke Langston.

REFUSE DISPOSAL.

NEXT after the removal of sewage from our towns comes that of getting rid of refuse, and few large towns are now without some practical means of dealing with a problem of

report, “is the use of the most modern and improved type of refuse destructors, together with sludge presses for reducing the semi-liquid sewage into dry, pressed cakes, which are just as combustible as ordinary ashpit refuse. With this fuel, supplemented by a moderate quantity of domestic refuse, these destructors will evolve a heat capable of raising enough steam in an ordinary boiler to supply a considerable engine power.”

Objection is taken to the old-fashioned destructors in Salford and Broughton, on account of the heavy, moist fumes they throw out. The new scheme is illustrated in the report by drawings of the destructor furnaces, boilers, and dust-catching appliances, which we herewith reproduce. Referring first to the sludge-pressing process, the report enters into a detail of the cost of buildings, sludge-pipes, and presses,

PLAN

increasing difficulty. A new scheme having several novel features is now under the consideration of the River Conservancy Committee of the County Borough of Salford, introduced by its engineer, Mr. Joseph Corbett, and will probably be soon in operation. We have no confidence in the general applicability of one scheme: circumstances and conditions entirely alter cases. On the observance of this principle, the borough engineer of Salford has based his plans for the disposal of the sewage sludge and domestic refuse of that important borough. In reporting on the sewage sludge disposal and sewer ventilation, Mr. Corbett has taken into consideration the various concomitant interests, and has been enabled to suggest a combined scheme for the carrying out of several processes that must tend to an improved sanitary condition of the borough. We refer to the surveyor's report on the means of disposing of the sludge at the Salford sewage works, the means of disposing of domestic refuse and ventilating the main sewers, and of supplying steam to the sewage pumping engines. The “main base of my first scheme,” says the

steam-engines for treating 240 tons of wet sludge per day, the capital outlay being put at £5,500, or a total annual cost, including repairs, of £2,279, equal to 2s. 1d. per ton of sludge cake. The output from this process is estimated at about 48 tons per day of pressed sludge cake. The dealing with the refuse comes next. The illustrations we give will explain to our practical readers the nature of the destructor furnace proposed by Mr. Corbett. The Horsfall patent refuse furnace or destructor has been adopted. It economises labour, effects a more perfect combustion of the refuse, less consequent nuisance from effluvia, and principally gives a higher temperature in the furnace for raising steam. As will be noticed in the section, the steam boilers are worked by the heat from the flues, so that no heat is lost after doing its work in the furnace, the heat being greatly intensified by the means adopted in the construction of the fire-bars and the flues, and also by the powerful air-blast introduced through the channel shown at the side of the furnace. The apparatus may be explained thus: On looking

at the section, it will be seen that a capacious hopper, square in plan, is provided at the side of a covered roadway, through which refuse carts will be taken. There will be six of these hoppers in a row (see plan). The refuse will be tipped from the carts into the hopper, and slide into the furnaces, which have removable firebars actuated by a cam shaft at the output end. By this movement the refuse will be gradually advanced through the furnace, the movement of the firebars increasing in the hottest part so as to prevent any massing of clinkers or ashes. At the upper part of the furnace-arch it will be seen that apertures occur for the flame near the output end. Below the furnace is the ashpit, closed by doors, through which on an ash-truck the ashes can be removed into the centre tramway. The air blast is into the closed ashpit, the effect of which will be to increase the draught through the fire and produce a high temperature. The cost of the six Horsfall destructors, with blowers, &c., will be about £1,700, and the annual expense about £480. Above the sunk road tramway are two tubular boilers, 15ft. long and 7ft. diameter, each having 270 tubes of 3in. diameter. These are shown also in the longitudinal section. The boilers are to be worked at 65lb. pressure, and will save the coal now consumed for the old substituted boilers. It appears that about 30H.P. of steam can be produced from each furnace, which will consume about six tons of refuse per day. The power required for the air blast and for moving the fire bars will be about 2H.P. per cell, leaving 28H.P. per cell available, or for the six cells 168H.P. The report states that this power will be quite sufficient for the working of the sewage pumping-engines and also the sludge presses, and that the sludge from the sewage will suffice to provide all the fuel required.

On the other side of the cross section of apparatus is the dust-catching appliances. The old flue-chambers of destructors provided to catch the furnace dust carried by the draught of the chimney, have been found of little use, much of the flue dust being carried up the chimney and scattered over the neighbourhood. To avoid this nuisance the "Cyclone" patent dust collector has been applied. It is simply a conical-shaped vessel, with the apex downwards, into which the dust is carried by a blast of air. There is a tangential opening on one side near the upper part of cone, through which the dusty air enters, causing a whirling rotary movement, by which action the particles of dust are thrown against the sides of cyclone, and descend to a small outlet at the bottom, where they are received in a dust truck. The dust-freed air ascends through the vertical tube shown in the upper part of cone, and is led to the main chimney. By these cyclone dust catchers, of which four are shown in plan, the labour of flue cleaning is avoided, and the dust can be removed as shown. The cost of the four cyclones is put at £1,100.

Alluding to the means for ventilating the sewers, the engineer proposes that the two "Sturtevant" blowers required for the furnaces be arranged to draw air from the intercepting sewers, causing a strong current through them, and consuming any injurious germs or gases. The present openings at the sewer outfalls and those in manhole covers would be closed, so that all small vents would become inlets for fresh air.

The harmless hard burnt refuse produced from the furnaces it is proposed to tip on low ground, and as there is now nearly 30,000 tons annually to dispose of, the alternative plan is put forward of using the destructors for domestic refuse only, and of disposing of the sewage sludge by steamers to sea. The author suggests that, as the quantity of domestic refuse is continually increasing, a certain proportion (48 tons per day) of the refuse should be burnt in the destructors and the sewage sludge conveyed to sea on sludge steamers. The statement of cost of both schemes is important, though we cannot quote the figures here in detail. It is enough to state that the total value and estimate of first cost for pressing and burning sewage sludge is £9,350, and an annual expense of £3,558, showing a net annual saving of £172, or that 87,600 tons of sludge can be disposed of and steam supplied annually for 9½d. per ton; while the alternative scheme last mentioned gives a total first cost of £14,350, and a net annual saving of £2,610; or that 128,120 tons of sludge, domestic and trade refuse, can be annually disposed of, and steam supplied, for £1,159 a year, or at the rate of 7½d. per ton. The above scheme meets the diffi-

culty of refuse-disposal in a thorough and efficient manner, and at a cost that compares favourably with that expended in other towns.

THE ELECTRIC LIGHTING OF SMITHFIELD MARKETS.

A VERY important electric installation has been made by the Corporation of the City of London in connection with the lighting of the Central Markets, Smithfield. The contract has been taken by the well-known firm of electricians, Messrs. Julius Sax and Co., who have arranged an installation which promises to be a model of its kind in the City. The whole area of the markets to be lighted is seven and a half acres, at a cost of about £30,000, though only the poultry and provision sections are at present completed. The vast area of buildings and avenues, which were lighted for the first time on Friday evening by the Lady Mayoress, will form a brilliant centre of illumination in this not very well-lighted neighbourhood. The whole installation, when completed, will certainly be one of the largest in the country of a private character. A few figures will convey an idea of the extent of the work accomplished by Messrs. Sax and Co. The wiring is said to extend 40 miles in length, the number of lamps now lighted are, we believe, about 8,500, though the total number will be 12,000, and these are from 15 to 50 candle-power each. The arcades are lighted by incandescent lamps. Six dynamos with an output of 200 units each are required, worked by four engines of 200H.P. The tenants will be supplied, it is stated, at the same price as they pay for gas, the cost of the plant and fittings being defrayed by the Corporation. The switching on of the light by the Lady Mayoress, in the presence of a large number of civic functionaries and friends was unique in its way, and was performed by the opening of a leather case and the withdrawing of a gold paper-knife in the form of a dagger, which completed the circuit. This was presented to Lady Evans by Mrs. Sax, and the firm of Messrs. Sax and Co. afterwards entertained at the Dr. Butler's Head, Basinghall-street, a large number of Common Councillors, scientific gentlemen, and representatives of the Press to a dinner.

OBITUARY.

MR. JAMES WILLIAM WILD, for the past fourteen years the Curator of the Soane Museum, died, on Monday last, at the Museum residence, 13, Lincoln's Inn-fields, at the advanced age of 78 years. Mr. Wild was trained as an architect, and was the brother-in-law of the late Owen Jones. Many of his earlier works of half a century since excited considerable interest at the time, as they were clever adaptations of the Byzantine style, then little known to English architects. He was also well versed in Arabic art. Among his buildings were the church on Blackheath-hill, erected about 1838; that of St. Lawrence, Southampton (Early English, in white brick, with groined vestibule under the tower, to which a spire has since been added by Mr. A. Bedborough); Christ Church, Streatham-hill, built in 1841 (a white brick basilica, Lombardic-Byzantine in style); and St. Martin's parochial schools (since altered into a school of art) in Castle-street, Long Acre, built about 1850. Mr. Wild also carried out the British Embassy at Teheran, and St. Mark's Church, Alexandria; he recently designed and superintended additions and alterations to the Soane Museum. He was for many years one of the staff in the architectural department of South Kensington Museum; and in April, 1878, on the death of Mr. Joseph Bonomi, the Egyptologist, was elected to the post he held till his death. The appointment of the curator is vested in the president, council, and trustees of the Royal Academy.

Mr. Edward Graves, Engineer-in-Chief to the General Post Office, died on Wednesday, at his residence, Earl's Court. He had completed 40 years of telegraphic service, having commenced with the Electric Telegraph Company at York. After the transfer of the telegraph to the Government he acted for some years as divisional engineer, with headquarters at Birmingham; and on the retirement of the late Mr. Culley he was appointed to the office of Engineer-in-Chief. He was engaged at the General Post Office up till a few days ago.

The death of Mr. Henry J. Marten, M.Inst.C.E., took place at his residence, The Birches, Codsall, on Wednesday week, from an apoplectic seizure. The deceased had long been associated with many of the engineering and sanitary societies throughout the country, and he had been identified with a number of important engineering schemes. The Waterworks at Wolverhampton were constructed under his supervision forty years ago, and since then he had devoted much time to water supply and allied subjects. He was consulted respecting the promotion of numerous waterworks undertakings throughout the kingdom, and frequently gave evidence before Parliamentary committees on these matters. He was associated with the schemes brought forward from time to time to improve the navigation of the river Severn, and prepared a plan for improving the canal navigation between South Staffordshire and that river. The deceased had been for twelve years one of the arbitrators under the South Staffordshire Mines Drainage Acts. He joined the Institution of Civil Engineers more than forty years ago. Mr. Marten, who leaves a widow, son, and two daughters, was twice married, his first wife being a daughter of the late Mr. E. B. Dimmock, with whom he entered into partnership, and managed for some years the Parkfield Ironworks at the Rough Hills, Wolverhampton. On the dissolution of the partnership, however, Mr. Marten resumed his professional career as a civil engineer. The deceased was 65 years of age. He has two brothers—Mr. E. Bindon Marten, M.Inst.C.E., of Stourbridge, who is one of the engineers to the South Staffordshire Mines Drainage Commissioners, and Mr. A. G. Marten, Q.C.

BOOKS RECEIVED.

Fifty Years of the Water Cure, by JOSEPH CONSTANTINE (Manchester: John Heywood), is a record of the experiences of one who has been an indefatigable worker, an advocate of hydropathy, and the author of several works on the water cure. We have no space here to give the gist of Mr. Constantine's genially written book. In this work he mentions many interesting incidents in his early life: his connection with bathers and hydropathic treatment, his opening of baths at Manchester, the introduction of the Turkish bath; diet, exercise, and a variety of cases of successful cures in erysipelas, scarlet fever, rheumatic fever, gout and rheumatism, &c. Many of these are wonderful instances of the value of the curative power of hydropathy when thoroughly carried out, and the experiences and suggestions of the author are instructive. Portraits of the author and of Drs. Wilson, Gully, and Edward Johnson illustrate the text. The author's work on ventilation and warming by the convoluted stove may be remembered by many of our readers.—*The Practical Polish and Varnish Maker*, by H. C. STANDAGE, Practical Chemist, &c. (London: E. and F. N. Spon), is a treatise or compilation containing some 750 recipes and formula of a practical character, and intended for the manufacture of polishes, varnishes, lacquers, &c., for workers in wood and metal. We have seen some of the recipes before, and we find instances where the compiler has duplicated the same recipe, or has allowed more than one version of a recipe to appear. Notwithstanding these inadvertencies, almost inseparable from works containing so many hundreds of references, the book will be found of value to all wood and metal working industries, manufacturers, and to the public generally.

At a meeting of the Lancashire County Council on Friday the vice-chairman presented to the Right Hon. J. T. Hibbert, M.P., first chairman of the council, on behalf of his colleagues, a life-size portrait of himself, in recognition of his services to the county. The portrait, which has been painted by Mr. Sydney Hodges, R.A., will be hung in the county hall at Preston.

A parish-room at Ashford, East Kent, erected near the college and church, from designs by Mr. R. P. Day, diocesan architect, was formally opened and dedicated by the Bishop of Dover on the 31st ult.

The popular lectures at Firth College, Sheffield, were opened on Saturday evening by an illustrated lecture on "Architecture in Norman Times: a Story of Natural Progress," delivered by Dr. H. C. Sorby, F.R.S., F.S.A.

QUEEN MARY'S SUNDIAL, HOLYROOD PALACE.—BANK AT EASTBOURNE.—THE POWDER TOWER, PRAGUE.—ST. BARNABAS' PARISH CHURCH, DULWICH.—PUERTA DEL SOL, TOLEDO.—HOUSE AT NORTHWOOD.—HEREFORDSHIRE NOOKS AND CORNERS.

Our Illustrations.

QUEEN MARY'S SUNDIAL, HOLYROOD PALACE.

The ancient sundials of Scotland are justly celebrated for their variety and picturesqueness. Few, however, can compare with that which we fully illustrate to-day by Mr. R. W. C. Dick's measured drawing. In consequence of the top having been displaced some years ago, the panels were much damaged. The dial casts the time about a quarter of an hour slow by Edinburgh, but this defect no doubt is due to an error in the re-setting it in position. The curious devices on the panels are indicated by the detailed parts above the general drawings.

NEW PREMISES FOR THE LONDON AND COUNTY BANKING COMPANY, LIMITED, EASTBOURNE.

The building stands on a corner site opposite the railway station. The fronts are in red Mansfield stone and red brickwork. The work, including the bank fittings, has been carried out by Messrs. Parsons and Son, contractors, 118, Church-road, Hove, Brighton. Mr. E. Houghton was the clerk of works. The mosaic flooring was laid by Messrs. Mainzer and Kempthorne, of Berners-street, London. The wrought iron gates and railings were supplied by Messrs. Stodge and Co., Osnaburgh-street, London. The steel girders and joists were supplied by Messrs. Measures Bros. and Co., of Southwark-street, London. The architect is Mr. Fred. G. Cooke, of Eastbourne.

THE POWDER TOWER, PRAGUE.

The elevations and plan of this tower appeared in our issue for Oct. 28. To-day we give the sections which need no further description than that given with our previous illustrations, which, like these, were taken from the officially published monograph issued by the Mayor and Council of Prague as a memorial of the restoration of the tower, carried out at the cost of the Municipality by Mr. Joseph Mocker, architect.

ST. BARNABAS' PARISH CHURCH, DULWICH.

This church, now in course of erection, will comprise a chancel, having a morning chapel on the south side, and priests' and choir vestry on the north, the organ being placed in a loft over the choir vestry. The high altar is elevated by nine steps. The body of the church consists of nave and aisles with north and south porches, the latter having a muniment room over, access being obtained from the winding stair of the large tower which terminates the nave and forms a baptistery, the large west doorway of which will form an emergency exit. The heating will be by hot water, a boiler-house being provided under the priests' vestry. The materials are red brick and terracotta, with red stone for columns, window tracery, and internal dressings. The

roof will be covered with green slates. There will eventually be accommodation for 789 persons, but at present only the eastern half is being built, and the oak screen work to chancel, &c., is to be omitted. Messrs. Oliver and Leeson, of Newcastle-on-Tyne, are the architects.

HOUSE AT NORTHWOOD.

This house has lately been built at Northwood, near Pinner. The walls are faced with red bricks, and the roofs are tiled. The turret is rough-cast. The woodwork is painted white throughout, except the doors and shutters, which are bright green. The drawing from which this illustration is taken was hung in the last Royal Academy Exhibition. The work was carried out by Messrs. Chas. Brown and Sons, of Harefield, from the designs and under the superintendence of the architect, Mr. R. A. Briggs, F.R.I.B.A., of 2, Devonshire-square, E.C.

PUERTA DEL SOL, TOLEDO.

This illustration, from a water-colour drawing by Mr. A. Wallace Rimington, of Kensington, shows "the Gate of the Sun," the most famous of the projecting towers in the city walls of Toledo. Its age is not known, but presumably it dates from the early days of the 13th century. The finest gateway in the outer wall, Puerta de Visagra, was built *circa* 1108-26, and by examination the Puerta del Sol may be attributed to the above period. It is built of wrought and rough stone walling and brick combined in that mixed style peculiar to the Moorish type, as developed in Spanish national buildings. Over the entrance are the arms of the cathedral, with the B.V. Mary appearing to San Ildefonso. From the gateway a fine view is obtained over the Vega, and Mr. Rimington's charming study does his subject justice.

HEREFORD NOOKS AND CORNERS.

(See notice and sketches on pages 660-661.)

CHIPS.

Extensive structural alterations are to be made to the Old Kennel Church, Edinburgh, N.B. The work has been placed in the hands of Mr. J. Williams Dunford, M.S.A., architect, of 100c, Queen Victoria-street, London, E.C.

Some time since the bells of Pickwell Church, near Oldhills, were restored, and now a new clock has been erected to completely furnish the tower. The time is shown on a handsome dial 5ft. across, and the hours are struck upon the largest bell. The movement of the clock has been made to the designs of Lord Grimthorpe by John Smith and Sons, of Derby, who are also now making the great clock for St. Paul's Cathedral.

The new mission room, Nottingham, is being warmed and ventilated by means of Shorland's patent Manchester stoves, the same being supplied by Mr. E. H. Shorland, of Manchester.

A crematorium has just been opened at Manchester. It has been built from designs by Messrs. Salomons and Steinhilf, of that city, and the Roman mosaic floors and niches for the urns have been executed by Messrs. J. and H. Patteson, of Oxford-street, Manchester.

The City Commission of Sewers resolved, on Tuesday, to widen Blomfield-street to 45ft. throughout, the opportunity being presented by the pulling down of Finsbury Chapel. The improvement is estimated to cost £9,000.

In the dome of St. Paul's workmen are now engaged in placing statues in the niches that have been so long waiting for them. A marble statue of St. Chrysostom, heroic in size, the first of eight to be placed in the niches in the pendentives, has been successfully raised to its lofty position, 135ft. above the floor. The sculpture—the handiwork of Mr. Woodington—was in two parts, together weighing about four tons.

The Duchess of Devonshire laid on Friday the foundation-stone of the new Deaf and Dumb Institution at Derby. The site in Friargate consists of two acres, the building will accommodate 100 pupils, and the estimated cost is upwards of £12,000.

A smoking concert was given on Friday evening at St. James's Hall, by the members of the Surveyors' and Auctioneers' Clerks' Provident Association and their friends, when between 500 and 600 persons met, under the presidency of Mr. R. R. Collins. This Association provides for allowance to members in sickness, allowance on death, medical advice, superannuation of members over 70, relief of members in distress, and of widows and orphans. The invested funds of the association amount to £2,700.

COMPETITIONS.

BEXHILL-ON-SEA.—The assessor appointed by the local board to examine and report on the plans sent in for the proposed town-hall has reported that, with the exception of two of them, none can be carried out for the amount limited by the Bexhill local board (£3,300) with 10 per cent. added, and that, with regard to the remaining two, they have, in other respects, so failed in complying with the conditions that he could not recommend their adoption. He has therefore been unable, under the conditions specified, to make any award; but he suggested to the board the propriety of their increasing the estimated amount to be expended to £4,500. The board have decided to alter that condition in their instructions, in accordance with the assessor's recommendation, but without in any way pledging themselves to carry out the work, and without the 10 per cent. limit. Under these circumstances, the clerk to the local board has written to all the competitors, informing them of the change, and inquiring whether they are willing that the plans already deposited should be left for competition at the increased estimate of £4,500, or whether they desire to send in any alternative or additional plans, which in that case must be sent in on or before Monday next, the 14th inst. Some of the competitors have agreed to leave their plans to stand their chance; but others have replied, pointing out that the extended time (a fortnight) is quite insufficient for recasting the plans, and urging that a fresh competition on new lines would be more equitable.

BLACKBURN.—In connection with the Forward Movement of the Baptist denomination it was recently decided by the county division to erect a new chapel and school in Blackburn. Invitations were sent to the following architects to compete for same:—Messrs. Morley and Woodhouse, of Bradford; Mr. Baines, of London; Messrs. Stones and Gradwell, Messrs. Simpson and Duckworth, both of Blackburn; and Messrs. Briggs and Wolstenholme, of 3, Lord-street, Liverpool, and Richmond-terrace, Blackburn, all of whom complied with the invitation. The committee have unanimously selected the designs sent in by Messrs. Briggs and Wolstenholme, and building operations will be commenced without delay. The chapel will be situated at the corner of Granville-road and Leamington-street, being part of the field until recently used by the Blackburn Rovers' Football Club; it will accommodate 700 worshippers, and will be constructed of brick with stone dressings. It is in the Romanesque style of architecture. The cost, including the school building, will be over £5,000.

ILFORD.—A competition is now pending at Ilford, and 67 sets of designs have been sent in. The building contemplated comprises local board offices of the usual kind and a fire-engine house. The work probably will cost £5,000 or £6,000. The award has not yet been made, and the matter is in the hands of the assessor, Mr. G. T. Hine, F.R.I.B.A., the architect of Claybury Asylum.

At the inaugural meeting of the Yorkshire College Engineering Society, held last week, Mr. G. Watson, of Leeds, read a paper on "The Disposal of Town's Refuse." Mr. Watson denounced large ashpits and the accumulation of filth, and arrived at the conclusion that the burning of refuse, with its various defects, was the best method of getting rid of material detrimental to health.

The London County Council discussed on Tuesday the proposal of a joint committee that, in the Bill to authorise the construction of a new street from Holborn to the Strand, power shall be taken to tax "the ground values of property within the county of London." Ultimately it was resolved to add to the recommendation authority to prepare a separate Bill for creating an improvement rate on owners of property, and that out of such rate provision should be made for the payment of one moiety of the cost of improvements. Thus amended, the recommendation was adopted.

On Tuesday week the Bishop of St. Asaph consecrated the parish church of Hirnant, Montgomeryshire, which has been rebuilt on the site of the old church, of which the foundations only remain. The materials for the stone dressings and timbered roof of the new church were taken from the old parish church of Llanwddyn, which was dismantled, its walls being shattered by dynamite, and its foundations are now covered by the waters of Lake Vyrnwy. The architects were Messrs. Booth and Chadwick, of Manchester and Colwyn Bay, and the builder Mr. W. H. Thomas, of Oswestry.

WAYSIDE NOTES.

I AM glad to see that the School Board is about to give the "outside architect" a chance. General Moberly's proposal will be welcomed by those with a taste for designing board schools. Although the recommendation of the chairman of the Works Committee was not adopted, as it stood, by the Board, an amendment of Mr. L. Stanley was well received, and this promises to lead to a competition. We may therefore look for its announcement at an early date.

The reason for this move is not very apparent. Possibly the Board wants new ideas. We know how, at the first inauguration of the L.S.B., a competition was held, and thereby the Board got ideas that served them in good stead, and were cheap at 5 per cent. on the outlay on one school. There seems to be a lurking impression among members that the job now proposed should be done for less than 5 per cent. The amendment above referred to proposes that the Works Committee shall explain "whether it is proposed to pay an outside architect the usual professional commission of 5 per cent. on the cost of the building," also "whether the supervision of the work as it proceeds is to be under the assistant architect for buildings, and the other officers of the Board, or to be independent." I fancy that if the Board desires respectable architects to compete they had better say definitely that the winner of the competition shall carry out his own work, and that the assistant architect for buildings and other officers shall look after their own business.

Some architects have to put up with much; all with a little. Few have the experience of Messrs. Spalding and Cross at the new addition to the St. James's Baths and Washhouses, Golden-square. The miserable front to these baths may be known to many readers. The commissioners, however, would insist upon the new elevation repeating the old one; and now there is a double range of sham windows with blackened boards behind the glass, and a brick wall behind the boards. I can understand how, at this end of the nineteenth century, readers may be incredulous; but if hard of belief, I ask that they run up to the baths and see for themselves.

The Institution of Civil Engineers opened for the session with an able address from the President, Mr. Harrison Hayter, who spoke of many interesting engineering enterprises in canal, tunnel, and railway building.

Mr. MacVicar Anderson has run full-tilt against draughtsmanship, and done a good work. In his presidential address on Monday evening, Mr. Anderson called attention to this evil, which has grown as a sort of a parasite on the back of honest drawing. It will have surprised many that the president of the R.I.B.A. should have made no direct allusion to the topic of the hour; but perhaps the best way to treat the matter is to exhibit a masterly indifference. It must be owned, however, that many in high places in the Institute have concerned themselves with the complaints of the "Memorialists," and sooner or later there must be some notice taken of the *réchauffé* "Architecture—a Profession or an Art."

It seems rather hard to throw even tepid water on ability in draughtsman. Were the methods of an architect of to-day similar to those of a chief designer or architect of the middle ages, less draughtsmanship would be required. Nowadays the power of drawing well and beautifully is, whatever may be said, a *sine quâ non* for an architect. Great excellence in drawing, too, has this advantage: It leads the draughtsman to invariably design and conceive designs in *perspective*. No great architectural draughtsman draws by habit in elevation—that is to say, when he is scribbling, so to speak, his notions and fancies of architectural composition he naturally represents his ideas in perspective. The tiro will draw in elevation. It is impossible to overrate this habit of drawing and designing in perspective, for while the drawer of elevations may know nothing of the subtle effects of perspective, the faculty for designing in perspective includes the drawing of elevations, and a knowledge of the effect of an elevation in perspective. It is necessary to lay stress on *original design*, and explain that pictorial representation is not meant,

otherwise one might ask why a mere artist cannot, on this line of reasoning, also make an architectural elevation? Whereas we know that an artist who paints cathedral interiors has no faculty for designing, or representing geometrically, such subjects.

A diocesan architect, telling me of the fearful abortions in the way of design that come before him in his official capacity, and thinking of "ghosts" and competitions, said: "If I were assessor, I would have every one of the premiated architects in a room where there was a 'cock-loft.' They should then each prepare a drawing under my observation, stationed in the cock-loft." I told him that the idea seemed excellent, and that it should be duly imported into the "B. N."

I trust that readers saw the leader that appeared in the *Daily News* of the 1st inst., and dealt with the great book. The opening lines were curiously interesting:—"We are not very particular, but it cannot be said that the world is satisfied with its modern architecture. Go to Oxford, look at the old work down to the Jacobean age, and then look at the new at Merton, Balliol, and Christ Church." If there was innocence in the writer, and no bias towards or against any particular architect or school of architecture, it is odd that he should have thus opened his critique.

Mr. Prior's choice anecdotes were quoted. That touching the Gothic clerk, by the bye, will be a favourite one with readers of the essay. It appears that "drawings lately came before a society accompanied by a note from the architect, apologising for their meagreness on the score that 'his Gothic clerk had the influenza.'"

Mr. Prior should be an acquisition at an architects' dinner.

I had always imagined that the keeping of Gothic, Classic, and Queen Anne clerks was a pure invention of those of fervid imaginations. We shall have the plea of illness or indisposition of one or another of these specialist assistants an excuse good enough to put in the building papers soon, wherever an elevation of some city building does not come up to general expectation. It was my idea that specialist assistants were confined to the "washing" gentry. The office staff I always imagined to be quite cosmopolitan, and *au fait* at one style as another, a cathedral or prison making no difference, and being equally acceptable in the drawing office, whether in Classic or Gothic garb.

I have heard of mysterious changes in the style of even well-known architects when their head assistant has been changed. Mr. Blank has been a well-known worker in 13th-century Gothic, and of a sudden his head man leaves from some cause, and a new assistant appears. It certainly, in such cases, is a remarkable coincidence that Mr. Blank's style veers round like a weathercock, and his new jobs appear in the strictest of Classic dresses. I suppose it is because the new assistant has powers of persuasion, and brings his master round to his views. What other explanation is forthcoming? The idea that our good friend never does any of the designing himself, but leaves everything to his assistant, is not to be thought of for a moment. It is preposterous!

"Architecture—a Profession or an Art?" would have been a good title for a banner in the show of the 9th. Well supported by the "Memorialists," it could not but have proved an attractive feature to the public, and the profession would have attended the show to a man. It seems a chance missed.

GOTH.

The doubling of the short section of the Cornwall Railway between Par and St. Austell was commenced on Monday by the contractors, Messrs. Strachan, of Cardiff.

Memorial stones were laid on Thursday in last week of the Hope Presbyterian Chapel at Merthyr Tydfil, now being rebuilt from designs by Mr. Roderick. The building will be Gothic in style, and built of blue Pennant stone with Grindsel stone dressings. In the basement is a lecture-hall 49ft. 6in. by 38ft. 6in., and classrooms, and over these is the chapel, 60ft. by 39ft. in the clear, and seated on ground floor and gallery in pitch-pine. The contract has been taken at £3,200.

Engineering Notes.

SOCIETY OF ENGINEERS.—At a meeting of this society, held at the Town Hall, Westminster, on Monday evening, Mr. Joseph William Wilson, jun., president, in the chair, a paper was read by Mr. W. H. Holtum, chief engineer to the Great Northern Railway, on "The Use of Steel Needles in Driving a Tunnel at King's Cross." An additional tunnel, with approaches, has been opened at King's Cross this year for traffic. It is on the western side of the two older tunnels, the first of which was built in 1850. In length each is 527½ yards. The two newer tunnels have a clear width of 26ft., or 1ft. more than the original central tunnel. The three tunnels pass in a northerly direction, level beneath the Regent's Canal, which is supported upon cast-iron crown plates, carrying the clay puddled bed of the canal; thence the rail gradients rise 1 in 371 and 1 in 75 up to the north faces. In the new tunnel an opportunity presented itself for the introduction of a novel method for working out the excavation beneath steel bars, or needles having a thickness of only 2in., in the place of the ordinary timbering, which generally requires 18in. excess of excavation around the extrados in order to build the arch of the tunnel. The first needles used were those patented by Messrs. Jennings and Stannard. These needles were driven by means of screwjacks, and various contrivances were used to fill up the 2in. annular space left over the tunnel when the forward movement of the needles began, the plan ultimately adopted being that of running fine cement concrete along chases left at intervals within the outer ring of the tunnel arch, whereby the chase, as well as the space behind the advancing needles, became filled with an imperishable material, and the subsidence of the surface of ground used as a goods yard was reduced to a minimum not worth serious consideration. Trussed sills were used instead of the usual long rakers to the upper sills of the face-timbering, which left the temporary roads of the tunnel less obstructed, as well as leaving no raker holes in the invert to fill up afterwards. Another introduction, designed by Mr. E. Duncan, to obviate a tendency the needle had, at times, to drop out of place, was that of interlocking the needles so as to form an almost solid steel roofing of 2in. in thickness. Where underpinned piers interposed within the area of the proposed tunnel and prevented further driving, the steel needles were removed and timber bars were resorted to, and built in as the work proceeded. In conclusion, the author referred to the evident economy of this new method of driving tunnels or culverts. The engineer for the King's Cross Tunnel works was Mr. Richard Johnson, M.Inst.C.E., and the contractor was Mr. Henry Lovatt, of Wolverhampton.

CHIPS.

New Wesleyan schools are being built at Pensanoth, Cornwall. Mr. A. S. James, of that place, is the builder.

The Dean and Chapter of Wells are expending £700 in rearranging the cathedral organ, so that it may be as available for services in the nave as in the choir. Donations to the amount of nearly £300 have already been promised.

A new Empire Theatre of Varieties has just been built in Nicholson-street, Edinburgh, from designs by Mr. Frank Matcham, of London. The style is Oriental, both the external elevations and the decorations within being based on Indian motifs. Accommodation has been provided for 2,500, at a cost for construction of £25,000.

The foundation stone of the new gasometer which the Bristol Gas Company are about to erect at Barton-hill, in that city, has been laid this week. It will be one of the largest gasometers erected in the provinces, its capacity being 5½ million cubic feet, those already in existence in the city containing about 1½ million cubic feet. It will be 222ft. in diameter and 150ft. in height, with three lifts of 50ft. each. The contractors are Messrs. Aird and Sons, of Lambeth.

A public clock, with chimes, presented as a memorial to the late Mr. Elymas Wandsworth (County Councillor and first chairman of the Cleckheaton Town-hall Committee), by his two sons to the town of Cleckheaton, and erected in the tower of the new town-hall, was formally started on Saturday afternoon. Messrs. W. Potts and Sons, of Leeds, were the makers of the clock, which has three external dials, and is fitted with the Cambridge chimes.

Building Intelligence.

BATTERSEA.—The foundation stone of municipal buildings for Battersea was laid on Monday. The buildings will occupy the summit of Lavender-hill. The architect is Mr. E. W. Mountford, and the builder Mr. W. Wallis, of Balham. The buildings will cost over £26,000, and are Modern English Renaissance in style. The materials employed are red Suffolk bricks and Monk's Park (Bath) stone for the walls, the roofs being intended to be covered with thick green Westmoreland slates. The frontage to Lavender-hill is 110ft., the principal entrance being in the centre. The entrance hall measures 54ft. by 30ft., and round it are grouped offices for the transaction of the business of the Vestry and board of churchwardens and overseers. The grand staircase to the first floor springs from the entrance hall facing the vestibule, and will have balusters of pink Devonshire spar, the plinths and hand-rails being of polished Devonshire marble. The council chamber, which will occupy the front central position of the first floor, will be 54ft. by 35ft., and will have a committee room at each end. A large gallery is to be provided in the council chamber for the accommodation of the public, which will be approached by a separate staircase from a new street on the eastern side of the buildings, and by a corridor on the second floor. The large public hall is to be in the rear, with a separate grand entrance from the Town Hall-road, and will have other entrances also from this road, and from the footway which extends along the whole of the western side of the buildings. This hall will be 117ft. by 55ft. 6in., and will seat 1,200 persons. Beneath the large hall there will be a smaller hall measuring 55ft. by 38ft. The contractors for the whole of the constructional ironwork are Messrs. W. H. Lindsay, Neal, and Co., of Paddington Iron Works. We illustrated the buildings in our issue of Dec. 11, 1891.

BEXHILL-ON-SEA.—At the parish church of St. Peter last week, an altar, reredos, and other memorials were dedicated, and also a new organ, with oak case, built by Messrs. A. Hunter and Son, of High-street, Clapham, S.W. The various works have been carried out from designs and under the supervision of Mr. Thomas Garrett, F.R.I.B.A., of Percy-road, Shepherds' Bush. The reredos, with its wings, extending across the eastern end of the church, is of English oak. In a long recess above the super-altar is a representation of the Last Supper in high relief, and over this is continuous canopy work. The wings are of wainscot panelling. The reredos, sedilia, credence-table, and prayer-desk, all of carved oak, have been executed by Messrs. Harry Hems and Sons, of Exeter. The space within the sacrum has been laid with marble pavement, and is approached by marble steps, supplied by Messrs. Farmer and Brindley, of Westminster. The choir has been paved with coloured stones, including Portland, Hopton Wood, Newbiggin, and Warwick, by Mr. C. F. Bridgman. A wrought-iron screen and gates are the work of Mr. J. Avery, of Kilburn, and the Communion rail and altar ornaments are by Messrs. Hart, Son, and Peard, of Regent-street, W.

GATESHEAD-ON-TYNE.—The foundation stone of the new Ellison School, Hopper-street, was laid on Monday by the Mayoress. The school is to take the place of an old building in High street, and is part of a scheme for the extension of Holy Trinity Church. The contract for the school has been let for £1,150, and the estimated cost for the enlargement of the church is £3,000. The designs for the school show a building simple in treatment, and built of brick, with stone dressings. It will be at the east end of the church, and will be a one-story building. The architect is Mr. Stephen Piper, M.S.A., Westgate-road, Newcastle, and the contractors are Messrs. Anderson and Slater, Newcastle. The work will be completed in March next year.

GARTLOCH, GLASGOW.—The memorial-stone of the new asylum which is at present being erected at Gartloch, about six miles north-east of Glasgow, by the City of Glasgow District Lunacy Board, was laid on Tuesday. In 1889 the estate of Gartloch, consisting of 347 acres, was purchased by the board at a cost of £8,500, and in June two years later the work of erecting the new asylum was commenced. Messrs. Thomson and Sandilands, of Glasgow, are the architects. It is expected that other three years will elapse

before the building will be completed. Four of the principal wards of the asylum are now nearly finished, and the work of erecting the administrative and official buildings will next be taken in hand. Constructed on the pavilion plan, the asylum will consist of nine large blocks, all connected. The stone used is red sandstone, while the style is Early French. The cost is estimated at about £150,000, and there will be accommodation for over 500 patients. We illustrated the building by plans in our issue of Dec. 11, 1891.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—At the opening meeting of the session held on the 1st inst., the President (Mr. W. Hale, F.R.I.B.A.), in the course of his address, pointed out that the most notable thing accomplished by that association during the past year was the arrangement with the Birmingham Municipal School of Art, whereby the architectural work, while still remaining under the control of the able masters who had in the past conducted it, has been supplemented, and concentrated into a definite course of architectural study extending over a four-years course. There was great reason for congratulation in the facts that so able a lecturer as Mr. W. H. Bidlake had been found in the Association to undertake the special lectures on architectural design, and that his lectures had been so well attended. Though it has been impossible to do more this session than carry on the classes of design and construction, it was the wish of the council to see other special classes started as soon as the number of students able to attend them justified their institution.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The opening meeting of the Association was held in the Royal Institution, Princes-street, on Wednesday evening, Mr. W. Wybrow Robertson, president, in the chair. The prizes in connection with work classes for sessions 1891-92 having been distributed, the president delivered his opening address, taking as his subject our duty in respect to ancient buildings.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.—The opening paper of the session was read on the 8th inst. by Mr. J. B. Mitchell-Withers, F.R.I.B.A., its subject being "The Works of Sir Christopher Wren, with a few Notes on some of the Principal Domed Churches of Europe." The early history and education of the great architect was briefly sketched, after which the reader proceeded to deal with a few of his architectural works, commencing with the chapel of Pembroke College, Cambridge, his earliest building; the Sheldonian Theatre, Oxford; the well-known library in Neville's Court at Cambridge, and other minor works. From the numerous churches erected in London he selected the steeple of St. Mary-le-Bow, Cheap-side, and the interior of St. Stephen's, Walbrook, giving in each case the criticisms of the principal writers on architecture, notably those of Elmes, Fergusson, Gwilt, and Wightwick. The lecture was illustrated with a number of lantern slides. On the motion of Mr. C. Hadfield, seconded by Mr. H. W. Lockwood, a hearty vote of thanks was awarded to the lecturer.

CHIPS.

At the annual meeting of the West Ham Corporation on Wednesday, the retiring Mayor unveiled a life-sized portrait of the late Mr. John Meeson, the first mayor of the borough, painted by Mr. Granville Manton, of Westbourne-grove.

At Thursday's meeting of the London School Board it was reported that Mr. W. C. Beaumont had notified that he is in possession as receiver and manager of the firm of Messrs. J. W. Hobbs and Co., Limited, the contractors for the erection of the Choumert-road School, Peckham, and that the erection of the school is being continued by Mr. W. C. Beaumont.

At the meeting of the local board for Rothwell, West Riding, on Monday, the selection of Mr. F. Greenwood as surveyor and inspector was confirmed, the present surveyor, Mr. Lewis Starkie, having been appointed district surveyor under the Lincolnshire County Council. A suitable site having been purchased for the purpose, it was resolved that Messrs. T. H. and W. E. Richardson be appointed architects for the erection of the new board offices in Marsh-street. Mr. Cogill, of Stourton, was appointed architect for the infectious diseases hospital.

Correspondence.

REMAINS OF ANCIENT PAINTINGS AT CANTERBURY.

To the Editor of the BUILDING NEWS.

SIR,—It may interest your readers to have some description of the ancient mural paintings recently discovered in the Church of St. Nicholas, connected with the Lepers' Hospital at Harbledown, near Canterbury. Immediate steps being deemed necessary for the preservation of these paintings, the most important of any that have been uncovered here from their thick coat of whitewash, I have had a favourable opportunity of carefully examining the works while treating them with a preservative solution, this having as a first result a deepening and brightening effect upon the colours, and enabling one to decide from the details revealed that the subject represented was the Annunciation. The two figures are on opposite splay of the east window, and stand under canopies of ogee form, flesh, draperies, and ornament alike painted in black, outlined with white, on a dull-red ground, the bold and simple treatment employed reminding one not a little of a rubbing from some monumental brass. The angel to the left of the window, slightly the smaller figure, has one wing raised crossing behind the white nimbus; the right wing turns towards the edge of the splay, and is rather indefinite. As the right arm crosses the figure, there is a blank space cutting off the raised hand at the wrist; this gap perhaps indicates that once there was the return of a scroll here, vestiges of which appear depending by the side of the gathered robe, although there is no inscription discernible to make the suggestion a certainty. The figure of the Blessed Virgin is as well posed as that of the angel; a book is clasped upon her breast, while at her feet, a little to the right, is a vase of considerable size, one handle of which forms a conspicuous element in the design. From the vase a blank space reaches to the Virgin's elbow, but here a flower and bud indicate an origin in the vase below. More confirmatory of the nature of the subject still is the emblem of the Holy Spirit a little to the right of the nimbus, and placed as though the Dove came from the window.

These paintings were probably executed in the 14th century, possibly soon after the chancel was reconstructed. It may be remembered that westward the style of the church is generally Norman.

I may mention also here that the doubt as to the nature of the subject painted on the south wall of St. Alphege Church, Canterbury, seems likely to be cleared up. This work having shown unmistakable signs of rapid disintegration, it has been treated with a preservative mixture. Under this details have become manifest that seem to indicate that any idea of connection with either the history of St. Alphege or St. Etheldreda must give way to the simpler explanation that the picture represents the Adoration of the Magi. It evidently covered at one time an area of wall that in later times has been pierced with a window. This painting is probably of 14th-century date.

The mural decorations in the hospital at East-bridge, which represent portions of a Martyrdom of Becket, a Last Supper, and Our Lord in Majesty with the Evangelical Emblems, have suffered much from exposure to the air since their discovery in 1879 behind and above the old fireplace, now removed, and their structural restoration by Mr. Neale. Fading gradually but surely away, these works have shown some signs of revivification under similar treatment to the paintings at St. Alphege and St. Nicholas.—I am, &c., PHILIP H. NEWMAN.
21, Endsleigh-gardens, N.W.

OPENINGS FOR THE ART WORKMAN.

SIR,—I read the article in your issue of the 28th ult. with much interest; but the question at once presented itself—Does the art workman exist? There may be a few lingering specimens of this genus, but as a race the art workman is dead. There are too many opposing factors at work to admit of his cultivation. Trade Unionism does not encourage the production of the artist. Competition is against his growth. The pace at which we live will not admit of his development, except in isolated cases, too isolated to count on.

The true art workman was the man who conceived and executed his own conception, instead of murdering someone else's. He corrected and remodelled it where necessary as it progressed, sparing neither time nor thought in its production; such men are inconsistent with the present age. The times do not produce them, or, if they do, starve their own offsprings. We must recognise the fact that we live in a mechanical age, and, having recognised it, take the best means of utilising what we have. It is an age of machinery, and man has adapted himself to the age, and, generally speaking, becomes a machine, with all its hardness, and little of its accuracy.

The few artists, instead of being art craftsmen, must be the machinists, to influence and guide the mechanical powers at their command.

The state of many manufactures, as you say, is deplorable, and much of the obtrusive worthlessness is due to modern innovations. Amongst them the "exhibitions" have done much to foster the abandon of the "ornamentist." Manufacturers, instead of considering the common fitness of things, have vied with each other to attract attention where all is obtrusive, with the inevitable result of producing vulgar novelties, instead of art products. The gigantic show-rooms are a milder form of this evil. Everything may be artistic if kept subordinate to its use; but exhibitions, show-rooms, and plate-glass windows are opposed to this essential art maxim, because their one object is an assertive one.

The designer is not wholly to blame; he has to live, and the designer of the manufacturer is too often only a draughtsman, without practical knowledge or experience. What is wanted is that the designer should be the ruling spirit, not the servant. It is difficult for him to combat popular taste or fashion, much more difficult if he has to do this through a third and interested agent. The demands of the manufacturers are, Give us something that will sell, never mind whether it is true to art principles. The one object of the age is to make money.

You speak of the ironfounder's mixture of Gothic and Classic details in the same article, and wonder why it is so. Generally the answer is simple enough. He has a Classic pattern and a Gothic pattern; his customers want a new design—they always do—and want it cheap. To meet this demand he cannot pay for design or pattern-making, so the bad patterns of existing articles are cut up, and a little of this and a little of that is used until a "new and original" article is produced, without the necessary expenses. This is one cause for the heterogeneous things called ornamental metal-work. It is not confined to the ironfounder; but you must not blame the manufacturer for covering his cheapest products with a multitude of bad ornament. Ornament covers and hides bad work; bad ornament is cheaper than good, as weeds cost less to produce than stove plants. If you want plain things, you will necessarily have to pay a little more for them. Firstly, the material and workmanship must be better. It is this exacting demand for cheapness that must be held responsible for some of the monstrosities. Mantel shams are produced as low as 3s. 4d. each retail. Can you expect an art product for this sum?

Your argument that the general run of stoves are spoilt by over-ornamentation is good, and in the more expensive work is unanswerable. Yet there are plenty of good designs at a fair and moderate cost; but your everyday builders' ironmonger will not have them; they are not attractive and assertive enough for his show-rooms, and they do cost a little more in consequence. Pattern-making is an expensive process; the cost of patterns has to be spread over the number sold; and it is a deplorable fact that the general public likes plenty for its money, whether in ornament or other things, and the builders' ironmonger recognises this in his selection of stock. Consequently the educated taste must pay a little more for its specialities, because its requirements are small as compared with the wants of the legion of the uneducated. As another example of vitiated taste, take the enamel slate chimney-pieces. Why do these sell? There may be an excuse for the cheaper productions in this material; but why do the expensive things get into houses that have cost over £1,000 to build, chimneypieces retailed at £7 to £10? The answer is, because the gaudy inclination of an inartistic age wants ostentation, not art; its appetite is ravenous, not epicurian. The fault lies with the consumer. Good designs in cast iron

can be had at fair prices; but in this, as in other things, if you want bulk you must take an inferior quality. Still I agree with you, the general ironfounder is not an artist, nor, on the other hand, is he a philanthropist. He is what the times have made him. If you had an artistic people, artistic ironfounders would follow as a matter of course.

You say wrought-iron work is taking the place of cast for the fireplace. I am as much interested in wrought as cast iron, yet I think it is a bad change from a practical point of view. You would not advocate the use of wrought iron on the sea-coast for outdoor work. For an equally practical reason, cast iron is better for the firegrate; its skin is harder, it does not scale, nor is it so liable to twist under heat. Many of the wrought-iron productions of the present time, though pleasant to look upon, are not serviceable, being altogether too light for practical use; therefore, from the soundest of all art doctrines, "the common fitness of things," they are not artistic.

It is the same influence that is at work in the marble trade. As you say, the ugly trusses do not support the shelf; they are placed there to satisfy the consumers' desire for something bulky and ostentatious. If they were structurally introduced, they would necessarily cost more than those stuck on with plaster, and would cease to be a saleable commodity on a large scale, against their dishonest rivals. There is even a more hideous form of marble mantelpiece being sold to-day in thousands (the marble trade is by no means dead). The truss is replaced by what is known as a drop column. This is comprised of a square block of white marble, with a red pimple on its face, then a pretence of a moulding, then a short column of alabaster, or yellow, finishing with a lump of white with a second pimple. This would-be shelf support is made of about ten pieces of marble, and most of these chimneypieces are produced, not by machinery, but by the hands of English masons, not even imported from Belgium.

The age is an economic (?) age; marble to be worked on your lines is not a cheap material, and until the public are prepared to be more generous they will have to put up with the false construction, or leave marble chimneypieces alone.

Marble can be used to advantage, and economically, by making more of a feature of it in the linings or interiors of wood chimneypieces, where it would be useful, ornamental, and honest.

We do not live in an art age, nor can I agree with the optimists that there is any material improvement in the public taste. There appeared to be an improvement some years ago; plain goods were eagerly sought after, and everyone was talking too too utter art nonsense. Manufacturers were naming their goods with nomenclature that might have been Hebrew from any significance it had to their minds, except as a catch phrase; but it was all a craze, all a fashion. The same motley crew are now rushing after the Rococo with the same eagerness that they sought the so-called Early English. Satiated for a time, they took plain food; the nausea passed, and they are ready to swallow the most offensive art diet you can give them.

But, sir, the architect who can perpetrate such designs as the drawing-room designated "Free Classic in Extremis," illustrated in the same issue as your article, is far more responsible than the ironfounders, who do such things "because they know no better," and I regret that your condemnation was not an unqualified one. This craze for Rococo has been growing for some years. The cabinet-makers and upholsterers caught the complaint at the Paris Exhibition, and it has been spreading from trade to trade, until, as I learn from your valuable paper, the profession has caught it, like the doctors catch influenza. Still it is not a thing to despair over. Let us give those who will have it good work, fit for its uses; the others will go their own gait, and wallow in their own abominations.

"For every evil under the sun
There is a remedy, or there is none,
If there is one, try to find it;
If there is none, never mind it."

—I am, &c., JOHN WARD.
24, Quadrant-chambers, Birmingham.

A branch of the General Union of Operative Carpenters and Joiners was formed last week at Tunbridge Wells.

Intercommunication.

QUESTIONS.

[10883].—**Spring Ball-Room Floor.**—Will someone kindly give me information with reference to the following:—(a) What is the best method of constructing a spring ball-room floor? Size of room about 85ft. by 25ft. (b) What was the method used from 12th to 15th centuries in heating the old churches, or where could I obtain information with regard to this subject? (c) What books on drainage is it advisable for an architect to study in addition to Baldwin Latham and Hellyer?—P. Q.

[10884].—**Framing.**—What is the best method of sanding external wooden framing, so as to resemble stonework?—R.

[10885].—**Ants.**—An alteration was made to some premises annexing the adjoining property (a dwelling house), and building therein a patent baker's oven, which was covered with sand; ever since this oven was started the premises have been overrun with millions of small ants, until the place is infested with them. Whether or not the ants were brought in the sand is a question. I should be glad if any of your readers can give me a recipe for exterminating these pests?—BOTHARD.

REPLIES.

[10873].—**Boasting.**—Your correspondent "who does not mind telling" should be more careful, and first be sure that what he says is worth "telling." "Boasted," or, more properly, "bosted," work is not as he describes, but is the exact kind of work which he ascribes to the incompetent man, and is in many cases specified to be done to an angle of 45°. It is not done on any given number of "lines"—really "blows," to the inch. This is nearly always regulated by the texture of the stone used. If it is hard and fine there will be really more than 8 blows to the inch; if soft and more easily worked, very excellent bosting is done at 4 or 5 blows to the inch. The kind of work he describes as "boasting" is really known as "tooling." Fancy the extra labour and tediousness involved in covering an extensive surface with "lines" or "blows" with a tool 2½ in. or 2 in. wide. The work he describes as "boasting" is usually done with a tool 4 in. and up to 5 in. wide, thus securing more uniformity in the work. Bosted work is really chiselled, but the stone being first "broached" or pointed, and next dressed with a chisel about 1 in. wide, is then ready for "boasting." It is sometimes known as "dressing," but as masons call their wide tools (not too tools) "bosters," to distinguish them from others, it is more commonly called "boasting" or "bosting." This is the custom in the Midlands and the North of England. It is not so prevalent in the South on account of the extensive use of Oolite limestone, which are usually sawn and then "dragged" smooth. These are sometimes "bosted." The stones which are usually bosted are hard limestones and grits.—A MASON.

[10878].—**New Lights in Old Boundary Wall.** An adjoining owner has legally a perfect right to break out new windows in his boundary wall; but "Legal" has also a perfect right to prevent him seeing anything out of his new windows. From the information given on the plan, if "Legal" were to build anything on the yard he would block his own gateway and injure his own windows. The better plan would be to ask the adjoining owner for a yearly acknowledgment for use of light, and if he refuse, then to erect a high hoarding, blocking up the windows, but not touching the adjoining owner's wall.—GILBERT W.

[10879].—**Stucco Front.**—I am afraid that there is no binder which, if put into colour-wash, would make the same adhere to an old painted surface. The better plan for "S. A." would be to remove the old paint by means of one of the many preparations for that purpose, and then to apply the distemper. Let the distemper be washable, and the rain will not be able to wash it off. There are many washable distempers.—DEPUTY B. E.

[10880].—**Fireproof Floors.**—Besides the better-known patented systems of fireproof floors, iron or steel joists embedded in concrete are much used. A better and more economical method of constructing concrete floors, which eliminates the destructive iron girder, is described in my specification of Letters Patent No. 1415, 1892.—F. G. E.

[10882].—**Water-Pipes.**—"Inquirer," Messrs. E. Walker and Co., of High-street, Heckmondwike, Yorks, are the patentees of a tin-lined high-pressure water-pipe, termed "the health pipe," which has been found to resist the actions of waters brought from all parts of Great Britain and Ireland. High authorities on the pollution of water by lead have certified there is no action by water on the tin used in the lining of these pipes, which are tested to resist an extremely high pressure.—HY. STEAD.

[10882].—**Water Pipes.**—Several methods have been proposed for coating and lining the insides of lead pipes to prevent the water conveyed from acting upon them. Most of them are objectionable, though, of course, some are successful. Among the latter are the following:—Schwartz's patent: The pipe is boiled in sulphide of soda for 15 minutes, by which the interior is coated with sulphide of lead (a substance insoluble in water). Haine's patent: This consists of an inner pipe of block tin, encased in a lead pipe. The two metals are so united that no joint between them is perceptible, and they cannot be separated by any amount of bending or twisting. In consequence of the tin melting at a lower temperature than the lead, it is somewhat difficult to make a soldered joint in these pipes; however, it may be done with care. This tin-lined pipe has been found to be entirely successful where the water is so soft that it acts upon lead. As these pipes are stronger than ordinary pipe, it may be of less weight per yard for water supply for any given pressure. "Inquirer" will find the whole subject discussed in Parkes's "Hygiene," and in "Lead Poisoning of Water and Its Prevention," by A. McGordon.—DEPUTY B. E.

[10882].—**Water Pipes.**—I should say patent lead-lined block-tin pipe, providing care is used in making

the joints. Galvanised wrought-iron tubes are frequently used; it is said, however, that some waters act on the galvanising. Glass-lined pipes can also be procured, and I should be glad if some reader who has had experience with them would give his opinion.—N. B. D.

CHIPS.

On Sunday, November 8, the Bishop of Reading dedicated a new reredos, which has been erected in the church of St. Mary, Tingewick, near Buckingham. The reredos, which is carved in oak, has been executed by Mr. Harcourt Runnacles, of Halstead, from the designs of Mr. A. Blomfield Jackson, architect, London.

The trustees of SS. Saviour and Jude, at Anfield, have adopted a plan by Mr. T. G. Ebdy for the rebuilding of the church. The church when erected will easily accommodate 650. Mr. Ebdy's proposal is to take down the present church (but without numbering the stones), to put the red sandstone, which will not stand the weather, inside throughout, build the exterior with random freestone, and adopt Geometrical Gothic, using the columns, arches, and other dressings of the present church for the interior.

The central portion of the modern Caen stone reredos of St. John's Church, Cardiff, has been left vacant and uncompleted since the reopening of the church after restoration in 1887. This has now been filled in, at a cost of £600, with figures two-thirds life size, under canopies emblematical of five dispensations of the revealed faith. In the central niche is our Lord as Melchisedech, and in the side panels are Abraham, Aaron, Isaiah, and Peter. The work has been executed by Mr. W. Goscombe John.

At Marylebone, on Saturday, a German-Pole, Roman Marweg, brought upon remand, was committed for trial on a charge of throwing sulphuric acid on Richard Graefe, cabinet maker, of Bessborough-street, Pimlico, his former employer. Owing to a dispute Marweg was discharged. He went to his late employer's house, and threw some vitriol into Mr. Graefe's face, who was much burned, and lost his right eye.

The Mayor of Newport, Mon., cut on Monday the first sod of the public park presented to the town by Lord Tredegar. The site—2½ acres in extent—has a value of over £30,000 for building purposes. The Corporation have agreed to spend £12,000 in laying it out.

The Cornwall County Council have before them a report from the Highway Committee recommending that the county be divided into five separate highway areas—the three eastern areas to be under the superintendence of Mr. Jenkin, and the two western area under Mr. Hickes; and that a sub-inspector be appointed at £150 per annum for each highway areas, to act under the directions of the respective county surveyors. The committee also recommended that Mr. Jenkin be paid an inclusive salary of £350 per annum as county bridges and main roads surveyor, and Mr. Hickes an inclusive salary of £250 per annum for the like duties.

A bust of Mr. W. E. Morrison, for the past three years Mayor of Eastbourne, was formally placed in a niche on the staircase of the Town-hall on Friday as a permanent memorial of two years of office. It is heroic in size, and has been executed in Carrara marble by Mr. A. Bruce Joy.

Mr. Roberts, C.E., with Mr. William Burns, the law agent of the company, and staff, have completed the preliminary survey of the proposed extension of the Highland Railway from Stromeferry to Kyleakin, opposite the Isle of Skye, and an application will be made at the earliest opportunity to Parliament for the necessary powers.

One of the features of the coming Winter Exhibition of the Royal Academy will be some representative drawings in colours by Edward Calvert, the friend of Samuel Palmer, John Linnell, and others of Blake's set.

The Runcorn improvement commissioners and the Widnes local Board have each unanimously resolved to contribute £30,000 towards the cost of the proposed bridge to cross the Mersey between Widnes and Runcorn, on condition that the County Councils of Lancashire and Cheshire provide the remainder of the cost. The estimate for the scheme is £180,000, of which £140,000 is put down for the structure, and the remaining £40,000 for Parliamentary expenses, and compensation for property to be purchased.

The directors of the newly-established South Wales and West of England Iron Girder Company paid a visit of inspection on Thursday in last week to the works on the East Moors, Cardiff.

A mission-church at Mylor Bridge, Cornwall, was opened last week. It is seated for 240 persons, and has been built from designs by Mr. H. C. Rogers. On the retable is a cross by Mr. Harry Hems, of Exeter, carved out of one piece of oak, and having the crown of thorns surmounted by the crown of glory.

Legal.

SURVEYORS AND MORTGAGES.

WHERE a capitalist advances to a builder upon premises in course of erection, and takes a mortgage to secure himself from the building owner, he should, of course, employ a surveyor upon his own account on whom he can rely. If he does this, and the surveyor is guilty of negligence, the mortgagee will, at all events, have an action for damages against him. But if the man lending the money is unwise enough to act upon the report of the surveyor who is employed by and on behalf of the mortgagor, then the mortgagee will have no remedy in the case of gross negligence so long as no fraud is shown. This state of things was well illustrated in the recent and important case of "Dennes v. Gould" (*Times*, Oct. 31). There one Hunt, a building owner, made a contract with a builder to put up certain houses at Ilfracombe; but having no money himself with which to finance the builder, he obtained advances from the plaintiff, to whom he mortgaged the property. But instead of stipulating that he should only advance upon certificates of some surveyor employed by and answerable to himself, Dennes agreed to accept the report of the defendant Gould, who was the surveyor engaged by the building owner. It was proved that the defendant gave his certificates with great carelessness, and at the hearing before the Official Receiver he was found guilty of gross negligence, though not of fraud, and damages to the extent of £300 were awarded to the plaintiff. But then the objection was taken that there was no contract between the plaintiff as mortgagee and the defendant as surveyor; and so there could be no legal liability, as was decided by the Court of Appeal in the recent case of "Scholes v. Brook" (64 *Law Times*, N.S. 674). It was argued on behalf of the plaintiff that, as the surveyor knew perfectly well he was giving his certificates for the plaintiff to advance upon, especially as he had actually witnessed the execution of the deed of mortgage, there was a duty from the surveyor to the mortgagee, for default as to which he should be made legally liable in damages. But the Court, composed of Justices Wills and Collins, followed the earlier authority quoted. They also held that Hunt, as mortgagor, had employed Gould as the surveyor, and his certificates had been accepted by Dennes, who made the advances. The Court of Appeal had laid it down that there must be a contract of employment between a mortgagee and a surveyor to make the latter liable for loss. If fraud were shown against a valuer in such a case, he could be held responsible as for a false representation. But here, although gross negligence was found, it was not fraudulent, and for this, in the absence of a contract between them, the defendant could not be sued by the plaintiff, who must accordingly put up with his loss.

FRED. WETHERFIELD, Solicitor.

1, Gresham Buildings, Guildhall, E.C.

NOTE.—All questions for reply in this column must be headed "BUILDING NEWS," and must reach my offices, as above, by Tuesday morning to insure answer same week.

QUINTUS MEUS.—BUILDING.—NEIGHBOUR.—Next-door neighbours in town must put up with a good deal of noise and annoyance, and you are legally entitled to alter and repair your own premises, provided that you do the work in a usual and reasonable manner, and at the ordinary times, so as not to become a nuisance.

OWNER.—LEASEHOLDS.—REPAIRS.—As you have let repairs go so long, you can wait until expiration of leases, and then send surveyor. But if there is any danger of loss by the delay you should send in at once under the other powers of entry, and serve notices to repair in accordance with the covenants. You will also be able to go in at end of term and claim for dilapidations afterwards if the repairs are not done.

FAIRPLAY.—TIMBER STAGE.—BUILDING.—The case to which you refer was dealt with in my article headed "What is a 'Building'?" in the *Building News* for Sept. 23, 1892, where a timber stage, partly used as a shop, was held to be a "building" within the Act. Yours appears only to be a stage in connection with a workshop. But all these cases are questions of fact for the decision of the magistrate, though you do not seem to me to be liable.

S. J. R.—PRIVATE STREET WORKS ACT, 1892.—CONSTRUCTION.—As to Section 20, as the word used is "shall," I think the local authority must take it over as required, unless they can show it is not a "street" within the Act, and unfortunately the old definition of the Act of 1875 has not been made clearer. As to Section 22: 1. No. I do not consider the Canal Company would be liable for any portion. 2. They would then be liable as frontagers in accordance with the Act of 1875 and the

cases thereon. 3. The Act only exempts a railway or canal company, as I understand it, for the public good, and I do not think the exemption would extend to private persons in regard to an "arm" of a canal used by them. But, of course, this is an entirely new statute, about which opinions will probably differ.

LEGAL INTELLIGENCE.

PAINTERS CLAIM, AND GET THE STANDARD WAGE.—At West London Police-court, on Tuesday, Mr. Plowden heard three summonses against Mr. David Charteris, a builder and contractor, with respect to the non-payment of the balances of wages claimed by three painters. The men were employed at William-street Board School, the defendant being the contractor for the work, and they claimed to be paid at the rate of 8d. per hour, according to the trade-union rate. It was stated that all School Board work was paid at the rate of 8d. per hour. That was disputed by the defendant, who handed in some time-sheets to show that he paid at the rate of 7½d. per hour. He said leading men received 8d.; but common painters 7½d. only. He did not stipulate to pay the trade-union wages. He had paid the same rate of wages for School Board work for three years.—A clerk of the works in the service of the Board handed in a copy of the contract. There was a footnote governing the trade-union rate of wages. Other contractors signed the conditions, and he believed all other contractors paid at the rate of 8d. per hour.—The defendant said his attention was not called to the footnote of the contract, or he should not have signed the contract. He objected to the Board's dictating between him and his men.—Mr. Plowden said the footnote in the copy of the contract put the defendant entirely out of court. He made an order for the payment of the amounts claimed, with 10s. costs in each case.

SURVEYOR'S ACTION FOR LIBEL.—In the Queen's Bench, on Tuesday, Alfred Moser Hiscocks, the surveyor to the Vestry of St. George the Martyr, Southwark, brought an action for libel against Levi Joseph Dunham, the clerk to the Vestry of St. Mary Newington. The vestry of Newington have a contract with the vestry of St. George, under which the former deal with the street-sweepings of the two parishes at their depot. In a letter to his vestry clerk, defendant used words which plaintiff said imputed that he had some interest in getting the work handed over to a private contractor—a course which had been followed before. The defendant denied that the meaning which plaintiff attached to his words was correct, and pleaded privilege. A settlement was arrived at in court, defendant's counsel repudiating, on his client's behalf, any intention to impute that plaintiff was interested in any contractor or contract, or had done anything unworthy of his office.—A juror was then withdrawn.

EXISTING STREETS AND THE METROPOLITAN BUILDING ACT OF 1878.—ELLIS V. LONDON COUNTY COUNCIL.—This case resulted from the practice of turning residences into shops and using the gardens as the sites of the shops, and turned on the provisions of the Building Act of 1878 as to putting forward the boundary of the forecourt so as to be at a less distance from the centre of the road than is required by the Act. It was an appeal on a case stated against an order of the stipendiary magistrate for Woolwich, under the Act of 1878 (41 and 42 Vic. c. 32, s. 6), requiring the appellant to set back the external fences or boundary of the forecourts or other spaces in front of certain houses or buildings to a distance of 20ft. from the centre of the roadway of Church-lane, Woolwich. The appellant was the owner of a dwelling-house and garden, Cedar Lodge, adjoining Church-lane, up to the time of the erection of shops. There were buildings in Church-lane (all on one side) before 1878, the time of the passing of the Metropolitan Building Act, section 6 of which has a proviso that the construction or extension of any house or building in or abutting upon any street existing, formed, or laid out for building at the time of the Act may be begun and completed as if the enactment had not been made. But the magistrate found that Church-lane was not a street existing at the time of the Act of 1878. In 1855 some houses were erected, and in 1869 the whole frontage of land adjoining Church-lane, immediately to the south of Cedar-lodge, was divided into building plots, and building leases were granted, and in 1870 there were leases of a number of these plots and houses erected thereon. In 1878 about sixty houses were erected. In 1889 the wall of Cedar-lodge garden was pulled down, and a fence was erected on the site of the wall, and this was the fence in question. In 1891 shops were erected. The south blank wall was continued outwards by wall 6in. from boundary of appellant's wall. Between the garden wall and the boundary the fence in question was erected by the appellant on the top of the old wall. The magistrate found—(1) that the fence was part of an extended fence, a boundary of the forecourt or space in front of the appellant's southernmost shop; (2) that Church-lane was not a "street"
